It became clear some weeks ago that the Government's decision to discontinue the basic petrol ration would cause serious hardship to members of the medical profession. The registered medical practitioner is in a different position from other members of the community in that he is normally on call to his patients at all times of the day and night. Indeed, the doctor has become increasingly dependent upon his motor-car, and he is able to take a few hours' relaxation from his practice only because his car and essential medical equipment are immediately available to take him to an emergency call. Naturally the profession is expected to share with other sections of the community any hardships which arise from measures of retrenchment necessary in the national interest, but it is inequitable that doctors, because of their calling, should be denied some measure of social and recreational relaxation.

Representatives of the General Practice Committee have accordingly represented to the Minister of Fuel and Power that a doctor, when on reasonable call to his patients, should be permitted to use his car for any purpose. The Minister has recognized the special difficulties with which doctors are faced, though he has not been able to agree that doctors as a class should be subjected to no form of restriction in the use of petrol obtained on supplementary coupons. He has, however, agreed that if a doctor undertakes a social or recreational engagement and is at that time on call to his patients it would be reasonable for him to use his car in order that he might get to a case with the minimum of delay. In these circumstances, however, the doctor must be able to justify his action if challenged by the police. No doctor could justify the use of his car in circumstances where he had made alternative arrangements for his patients. Where a doctor using his car can show that he is on call to his patients and has taken steps to ensure that a message to which he can respond without delay can readily reach him it would, in the Ministry's view, be sufficient explanation that his car was being used in connexion with his professional duties.

Regional petroleum officers will be informed by the Ministry of these arrangements. It is understood that the police would not take any proceedings without prior consultation with the regional petroleum officer. It will be appreciated that the regional petroleum officer would not be in a position to express an opinion whether a doctor was in fact "on call" in any particular circumstances.

The Association has also learnt that regional petroleum officers have been instructed that petrol may be allowed to doctors for the purpose of attending meetings of the Association and other professional meetings in the locality. Where, for this purpose, the journeys involved are considerable the regional petroleum officer will consult the medical liaison officer as to the special importance of the meetings. The Ministry has agreed to look at any case where petrol has been refused for these purposes.

### "Doctor" Sign Available

Members who wish to affix a "Doctor" sign to the wind-screen of their cars should know that suitable labels are now available and have been issued to honorary secretaries of Divisions for distribution to those practitioners who require them.

## DOMICILIARY LIFE-INSURANCE EXAMINATIONS ON THE "SHORT" FORM

Early in 1947 agreement was reached for the standardization of a "short" form of medical report in connexion with life-insurance examination in respect of policies for amounts not exceeding £300, at a fee of 10s. 6d. Details of this form were published in the *Supplement* (Sept. 20, p. 69). Subsequently a number of inquiries were received from Members regarding adequacy of the fee in cases where the practitioner was required to visit the proposer for the purpose of conducting the examination. Negotiations on this question were resumed with the Industrial Life Offices' Association, which represents the large majority of the companies and societies that use the short

form of report. Although this Association has felt itself unable to recommend to its members that an additional fee should be paid where domiciliary examinations are required, it has suggested certain procedure which it is thought will materially reduce the number of such examinations and to that extent relieve the doctor of the necessity of visiting the property.

This procedure, which has been accepted by the Association for a trial period of twelve months, and which will take effect as from Jan. 1, 1948, is as follows:

(a) That it shall be an instruction to agents and district managers of the Industrial Assurance Offices that wherever possible arrangements shall be made for the examination to take place at the practitioner's surgery.

(b) That, where this is impracticable, authority for the practitioner to be requested to make a domiciliary examination must be obtained from the head office or regional office of the company or society.

(c) Where such authority is obtained, mileage shall be paid at the rate of 1s. per mile or part of a mile, each way, beyond a radius of 2 miles from the practitioner's surgery.

## HEARD AT HEADQUARTERS

### The Association's Handbook

The *Annual Handbook* of the Association for 1947-8 in its blue coat is a little stouter than its immediate predecessors, though it does not come up in size to the considerable volumes which were issued before the war. But it is what it says it is, a handbook, fitting nicely into the pocket, and indispensable for those who deal in any official way, centrally or peripherally, with Association affairs. It contains the usual list of honorary secretaries—as many as 365, from the Isle of Wight to Shetland, from Malta to Tasmania, from Jamaica to Ceylon. A new section of the *Handbook* concerns public-relations activities, and a list is given of 50 Divisions which now have honorary public-relations secretaries and a similar number in which the honorary secretary himself does public-relations work. At first these public-relations secretaries were appointed to act in the medico-political field in order to see that the profession's case was properly presented, or false statements corrected, in their local press, but many of them are now serving as liaison officers concerning health matters and medical progress in general. This is as it should be. It would be unfortunate if it came to be thought that the only point at which the profession has such desired contact with public opinion was when some medico-political issue was involved. Another feature of the *Handbook* is a list of the more important decisions of the Representative Body, some of them dating back for forty years.

### "Occupational Health"

The Industrial Medicine Committee of the Association, under Dr. Vaughan Jones's chairmanship, has been tackling the question of definitions. In framing an answer to a questionnaire from the Industrial Health Advisory Committee the definition of occupational health and the choice between that term and industrial health arose, and it was resolved to seek some advice on this subject. At its meeting the other day the committee had before it a dozen replies from eminent authorities in social and industrial medicine. All but one of them preferred "occupational health" to "industrial health," since the latter was considered likely to lead to misinterpretations. After all, it is the job a man does rather than the particular industry within which that occupation falls that has most to do with his health. One medical authority opened up the further question whether it should not be "occupational medicine" rather than occupational health. Of the definitions of the field of "occupational health" Lord Horder's was the most succinct: "The study of the causes, effects, and preventive and curative treatment of diseases arising from occupations, including their associated environment."

### Health Centres

We hear of a proposal by the West London Branch of the Socialist Medical Association, in conjunction with the Hammersmith Trades Council, to draw up a plan for the siting of health centres in Hammersmith. Doctors in that area will scarcely need to be reminded that, if only because of the building

situation, any such plan is premature at the present time, and that so far as the profession is concerned any local consultation regarding health centres is a matter for a professional body of a representative character. The whole subject of group practice is being examined by a special committee of the Association.

## Correspondence

### Married Doctors and the Services

SIR.—The following may be of interest to young married doctors about to enter the Services; to others it is an example of the method by which remuneration for professional ability will be awarded to the doctors of the National Health Service. Married commissioned officers in the three Services until recently received a marriage allowance of £7s. 6d. per week tax free. This allowance was stopped in the case of married officers under 25 years of age entering the Services after July 1946, and, after protest, was restored in part from Feb. 1 of this year. It was then decided that such officers could draw the marriage allowance allowed to the "other ranks"—viz. 45s. per week—and that from April 1 they could pay about half of it back again when marriage allowances became subject to income tax. Thus it is presumed that the young married doctor or professional man (there are the only people conscripted into a commission directly) can meet their professional, social, and commissioned-rank commitments on the same marriage allowance as an "other rank" or on half the allowance of any other married officer.

By dint of hard work I qualified shortly after my 22nd birthday, and when I entered the R.A.F. I already had one son; yet I found that a colleague qualifying nine months later and only just married was to receive almost double my allowance as he was over 25 years. Age and rank (closely related before ability and commitments would seem to be the order of the day. Might I suggest that those of my colleagues in a similar position (and there are many) arrange that their M.P.s are acquainted with the facts—"the usual Service channels" are the usual waste of time.—I am, etc.,

CONSCRIPTED R.A.F.V.R.

\* The R.M.A. Armed Forces Committee drew the attention of the three Service Departments to this matter last May. Each Department replied that it was out of the question to give a higher rate of pay or marriage allowance to the man called up for national service than is payable to the comparable officer holding a permanent commission. The non-regular officer is, however, at present eligible for a war-service grant in certain circumstances where he suffers financial hardship as a result of his service with the Forces. On Oct. 30 Mr. Alexander, replying to a question asked on Oct. 24 by Sir Ernest Graham-Little, said that the remuneration of officers under 25 did not compare unfavourably with that of civilians of similar age and qualifications. It was not, therefore, proposed to alter the present arrangement.—Ed., B.M.J.

### Working Hours in the N.H.S.

SIR.—Let people argue for or against State medicine as they please, but at least let their arguments bear some relation to reality. Sir Ernest Graham-Little (Nov. 15, p. 117) raises two points.

(1) He assumes that immediately "free" medical attention is available there will be an enormous increase in work. There is no evidence whatever for this assumption. Patients will presumably remain the same. Those whom you cannot stop working will continue to work until they are half dead before going to their doctor, just as they do at present. Those whom you cannot start working will, as now, be constantly on the doorstep. Panel patients are just as considerate and courteous (or, if you like, just as inconsiderate and discourteous) as private patients, no more and no less. I once read a letter in a medical journal of 1911 when the controversy over the about-to-be-introduced panel system was at its height. The author stated dogmatically, just like Sir Ernest Graham-Little, that there would be an enormous increase in work. He went on to

say that if a doctor had a thousand panel patients at least half of them would undoubtedly turn up at the surgery every day. Comment on this is unnecessary.

(2) Sir Ernest Graham-Little states that there are probably 50,000 doctors in active practice working at the present time, and that three times this number will be required under State medicine for eight-hour shifts. Does he not realize that in a town which normally keeps, say, twelve doctors busily at work during the day, the night work could easily be done by one person? Or does he really think that all G.P.s work as hard every night as they do during the day?—I am, etc.,

Morley, nr. Leeds.

W. STANLEY SYKES.

### Buying and Selling of Practices

SIR.—I have read with much interest the recent correspondence on the buying and selling of practices, a subject near to my heart and of paramount importance to every doctor in practice. I am in entire agreement with Drs. A. E. Moore (Oct. 25, p. 97) and J. H. Power (Nov. 22, p. 120), and I think Dr. S. H. Stewart (p. 120) has really missed the most important point—that the right to buy and sell, with consequent freedom to move to a different locality and the maintenance of our independence over this aspect of control, is the very essence of any freedom in the new Service. Only thus will any liberty remain to us.

Many young doctors feel a great attraction towards a scheme which will ostensibly hand out a ready-made practice on a silver platter, free of charge and liability. Will it in fact be so? If there is some financial easement, may it not be that their souls will be mortgaged instead of their pockets? Is "something for nothing" ever valued? Early struggles are well worth while if there is some goal to be reached, and the satisfaction in a good practice built up by hard work and possibly with some financial hardship in early days must be much greater than that ever to be attained as a ready-made unit in a Government-owned service.

Surely we, the first professional body to be attacked by dictatorship, will not surrender to such hysterical outbursts as "I will not permit, etc." For the sake of our country at the present time, as well as ourselves, we must resist this attempt to destroy individualism and the incentive to work.

I share Dr. C. H. Heaton's doubts (Nov. 15, p. 118) about the cohesion of the profession in any action taken under a plebiscite, and I think his suggestions of a legal agreement with a substantial sum as guarantee of good faith is a very excellent and necessary one.—I am, etc.,

Birmingham.

E. C. OSTLER.

### War Service and Hospital Appointments

SIR.—The warrior is not without honour—save in times of peace! In war, when the emotions are deeply stirred by danger and invasion threatens with its accompaniment of slaughter of the aged, slavery of workable adults, raping of women, and starvation of children, then are facile promises made. But, as "Ex-Service Doctor" (Nov. 8, p. 113) has discovered, when peace and logic return together and honour is too often put back in the cupboard, which is the better man for a hospital appointment—the foolish volunteer and unlucky conscript, or the man who stuck to his job like a leech? The man who had six glorious years of fun and world-wide travel at Government expense, little medical work, but plenty of leave and good food, or the man who carried on through thick and thin on the home "front" as registrar and junior consultant under the tutelage and appraising eye of his chief? Each did magnificent work in his own way, but in our brave new world, where lip service is paid to the dead and the best jobs are given to the best qualified, the answer is obvious.

There are hospitals still managed by men of honour, Englishmen whose word is their bond, but of these others mentioned by "Ex-Service Doctor" but rightly unnamed by him one feels the same cool cloud of disappointment as one felt on learning from the motor trade that doctors were no longer granted priority for cars because not few but many had used their wits, twisted their opportunity, and abused the privilege of priority for their own profit.

No, Sir; the one compensation for the years that the locusts have eaten in the lives of ex-Service men is the still small voice of conscience whispering wryly, "Well done, thou good and faithful servant." But it would appear that it profits a man more to-day if his conscience can mutter, "Smart work, thou sleek and clever savant." Having no axe to grind, as my hospital days are but memories, I write as a philosopher, a spectator of all time and all things. Maybe the profession does deserve the new State halter into which it is so busily, and secretly, having its neck thrust.—I am, etc.,

Dereham, Norfolk.

ERIC PUDDY.

### Monthly Panel Payments?

SIR.—For doctors depending mainly on their panel cheque to exist these days it will be a great boon to receive same every month instead of every three months as it stands at present. Few tradespeople would willingly wait for twelve weeks for their accounts, and I wish somebody would give a lead to approach the proper authorities with a view to altering our quarterly panel cheque to a monthly one.

Again, in view of the end of the basic ration of motor fuel, will it not be better for all doctors' cars to be marked back and front with a small yet visible red cross—say on the front window next to the registration-number disk and one on the back window? This will enable the police inspectors to recognize the vehicle, and perhaps save a lot of unnecessary questioning, etc., not to speak of the waste of time entailed.—I am, etc.,

Craghead, Co. Durham.

N. MUKERJI.

### MEDICAL WAR RELIEF FUND

#### SEVENTY-NINTH LIST

##### Individual Contributions

- £20.—Dr. D. T. Daintree, Bengal (7th donation).  
 £18 4s. 6d.—Dr. W. D. Steel, Worcester (3rd donation).  
 £5 5s.—Miss K. McArthur, Harrow (4th donation).  
 £5.—Mr. A. H. Asher, Inverness.  
 £2 2s.—Dr. H. H. Bloom, Boston, Lincs; Dr. A. G. McArthur, Kensington (5th donation); Dr. A. MacFaul, Leigh, Lincs (3rd donation).  
 £100.—Hon. Medical Staff, Birmingham Children's Hospital; Medical Staff, Harrow Hospital—per Dr. H. E. Thorn (amount already sent £310).  
 £85 11s.—Practitioners in Burton-on-Trent B.M.A. Division—per Dr. E. G. Frewer: Dr. G. Abbey £5 5s. (2nd donation); Mr. R. Bewick £5 5s. (2nd donation); Drs. Brindley and Crossley £10; Dr. J. Camac £5; Dr. N. J. Cochran £5 (2nd donation); Dr. J. M. Cowie £2 (2nd donation); Dr. J. W. Crawshaw £5 5s. (2nd donation); Dr. E. M. R. Frnzer £3 3s.; Drs. Lowe and Frewer £10 10s.; Dr. A. Macpherson £3 3s.; Dr. S. W. May £5 5s.; Drs. Pickett and Paterson £10 10s. (2nd donation); Dr. N. Mercy Plowright £5; Dr. R. C. Scott £5 (2nd donation); Dr. F. C. V. Thompson £5 5s. (2nd donation).  
 £53 15s. 1d.—Practitioners in Dumfries and Galloway B.M.A. Division—per Dr. J. G. McWhirter (amount already sent £100).  
 £50.—Practitioners in the Exeter B.M.A. Division—per Dr. M. Y. Paget (amount already sent £435 11s. 6d.).  
 £25.—Practitioners in the South Staffordshire B.M.A. Division—per Mr. Campbell Orr (amount already sent £74 6s.).  
 £15.—London Insurance Practitioners—per London Panel Committee (amount already sent £244 7s.): Dr. A. J. Clarke.  
 £11.—Practitioners in the Isle of Man B.M.A. Branch—per Dr. C. G. Pantin (amount already sent £256 9s. 6d.).  
 £2 2s.—Cardiganshire Medical Association—per Dr. D. L. Evans (amount already sent £116 19s.).

##### Local Medical and Panel Committees

- £606 2s.—Surrey (14th and 15th donations).  
 £113 14s. 4d.—Northumberland (4th donation).  
 £90 9s. 1d.—Ayr County (23rd donation).  
 £65 16s. 11d.—Dunbarton County (22nd donation).  
 £59 19s. 5d.—Breconshire.  
 £56 8s. 6d.—Newcastle-upon-Tyne (21st donation).  
 £30.—Oxfordshire (6th donation).  
 £5.—Norfolk (7th donation).

	£	s.	d.
Total of above contributions	1,524	13	10
Total received since issue of second appeal	24,577	8	2
Total since inauguration of Fund	83,230	17	7
Sums for books for prisoners of war	216	14	6

**Correction.**—In the Seventy-eighth List under the entry "£247.—Northamptonshire Medical Charity" the words "second donation" should have been entered after "Dr. S. E. Beilhell £2 2s." As already announced in the Supplement (Nov. 22, p. 121), the committee of the Fund considers it unnecessary for supporters to send further contributions.

Colonel V. N. Agate has retired.  
Lieutenant-Colonel D. Sanyal has retired.  
Lieutenant-Colonel C. F. J. Cropper, O.B.E., has retired on account of ill-health. (Substituted for the notification in the London Gazette dated June 20.)  
Majors A. M. Chaudhuri, O.B.E., H. J. Curran, J. H. Gorman, G. F. Condon, M. R. Sinfair, O.B.E., W. Happer, W. P. Ippin, O.B.E., W. McAdam, O.B.E., H. S. Smithwick, V. Srinivasan, H. T. McWilliams, B. J. Griffiths, M. H. Shah, N. S. Sandhu, I. Bakhsh, R. T. Hicks, O.B.E., A. M. Sheridan, K. Jilani, F. H. A. L. Davidson, D. H. Waldron, O.B.E., C. H. Dhala, S. Narain, F. M. Khan, D. Dutt, B. L. Taneja, W. J. Moody, H. D. R. Zscherpel.

M.B.E., Min Sein, A. E. Kingston, O.B.E., A. B. Guild, J. R. Dogra, R. C. Dracup, S. M. Kharegat, M. G. Saincher, and D. P. Nath to be Lieutenant-Colonels.

#### EMERGENCY COMMISSIONS

Captain G. T. Wallace has relinquished his commission, on being appointed to a Short Service Commission, British Service.

## Association Notices

### SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1, 1948. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the first award of the Insole Scholarship of the value of £250 for research into the causes and cure of venereal disease.

#### Conditions of Award: Applications

Applications for scholarships must be made not later than Friday, April 30, 1948, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

### Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition. The following are the regulations governing the award:

(1) The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.

(2) Any member of the Association who is engaged in general practice is eligible to compete for the prize.

(3) The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not therefore be omitted when it bears directly on their results, their interpretations, and their conclusions.

(4) Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual General Meeting of the Association to be held in 1948.

(5) No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prize-winner in any year is not eligible for a second award of the prize.

(6) If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay, the decision of the Council on any such point shall be final.

(7) Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

(8) The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

(9) Inquiries relative to the prize should be addressed to the Secretary.

### Nathaniel Bishop Harman Prize

The Council of the British Medical Association is prepared to consider a first award of the Nathaniel Bishop Harman Prize the year 1948. The value of the prize is approximately £100.

The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study essay that has previously been published in the medical press elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N. Ireland and not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1948 but will be offered again the year next following the decision, and in this event the money value of the prize on that occasion in question shall be such proportion of the accumulated income as the Council shall determine.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

The writer of the essay to whom the prize is awarded may be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

Essays must be forwarded to reach the Secretary, British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual Meeting of the Association to be held in 1948. Inquiries relative to the prize should be addressed to the Secretary.

CHARLES HILL,  
Secretary.

### Branch and Division Meetings to be Held

**COVENTRY DIVISION.**—At Coventry and Warwickshire Hospital Tuesday, Dec. 9, 8.30 p.m., B.M.A. Lecture by Dr. J. A. Gorsky: Medico-Legal Aspects of Some Murder Cases.

**HYDE DIVISION.**—At Hyde Municipal Offices, Wednesday, Dec. 10, 8.30 p.m. Dr. J. F. Ward: Abdominal Pain in Childhood.

**LEWISHAM DIVISION.**—At Lewisham Hospital, 390, High Street, London, S.E., Thursday, Dec. 11, 8.30 p.m. Dr. E. H. R. Smithard: Public Health and the G.P.

### Meetings of Branches and Divisions

#### STOCKTON-ON-TEES DIVISION

A scientific meeting of the Stockton Division of the B.M.A. was held on Nov. 3 at the Stockton and Thornaby Hospital. The lecturer, Sir Stanford Cade, was introduced by the chairman, Dr. W. M. Ritchie, and delivered an address on "Radiotherapy, Present and Future."

He began by giving some facts about the incidence of cancer and indicating the scope of surgery and radiotherapy respectively, stressing particularly the use of radium as opposed to x-ray therapy. He outlined the various methods of utilizing radium for therapeutic purposes in cancer and the effects of irradiation on plant, animal, and malignant tissues in controlling the rate of growth. He stressed the importance of dosage rate and the strikingly good results obtained in certain situations in the body by the use of radium in contrast to the futility of employing it in other situations. He briefly described possibilities for future therapy with radioactive isotopes and chemotherapy, and emphasized the probability that the latter provided a more fundamental method of attack on malignant disease than any other.

Mr. A. E. P. Parker proposed the vote of thanks.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

**County Borough Councils.**—Barnsley, Gateshead.

**Metropolitan Borough Councils.**—Fulham, Hackney, Poplar.

**Non-County Borough Councils.**—Dartford, Leyton, Redbridge (limited to future appointments), Tottenham, Walsend.

**Urban District Councils.**—Denton, Droylsden, Houghton, Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

**Scottish Burghs.**—Motherwell and Wishaw.

LONDON SATURDAY DECEMBER 13 1947

## PREVENTION OF RENAL DAMAGE BY USE OF MIXTURES OF SULPHONAMIDES\*

ANIMAL-EXPERIMENTAL AND CLINICAL STUDIES

BY

DAVID LEHR, M.D.†

Assistant Professor, Department of Medicine and Pharmacology, New York Medical College; Assistant Attending Physician, Flower and Fifth Avenue Hospitals, New York City

A new and simple approach to the prevention of concretum formation in the urinary tract caused by sulphonamides emerged from the observation that a saturated aqueous or urinary solution of one derivative of sulphanilamide could still be fully saturated with a second and third sulphonamide even if only of slightly different molecular structure, each of the compounds behaving as though it were present alone and exerting no influence on the solubility of the others. Consequently, in solutions containing several sulphonamides the maximum obtainable concentration appeared expressed by the additive solubilities of all individual drugs present (Lehr, 1945). This principle is illustrated in diagrammatic form in Fig. 1.

FIG. 1.—Diagram illustrating the individual and combined solubilities of sulphadiazine (SD), sulphathiazole (ST), and sulphamerazine (SMD) in water at room temperature (20° C.).

The figure elucidates the theoretical explanation of the phenomenon—namely, the specifically different molecular distribution in space of chemically different compounds. It also makes it clear that precipitation due to oversaturation will not occur more readily in the solution containing three sulphonamides, with a total concentration of 61 mg. per 100 ml., than in any one of the three individual solutions, with necessarily much lower maximum sulphonamide levels. Hence, at equal total sulphonamide concentrations the danger of precipitation will be significantly smaller in solutions of sulphonamide mixtures; it follows, in addition, that any increase in the number of components comprising a sulphonamide mixture will further diminish the chances of precipitation.

It was reasoned on the basis of this observation that the danger of the formation of sulphonamide crystals in the renal tubules could be considerably reduced by employing combinations of partial dosages of two or three

therapeutically equivalent sulphonamides rather than the full dosage of any one single compound. Actually the hazard of precipitation from such combinations should be only as great as if each sulphonamide had been administered alone and in the partial dosage contained in the mixture.

### Results of Animal Experimental Studies

Comparative studies of the toxicity and of the absorption and excretion of sulphonamide mixtures and their individual constituents were carried out on 750 albino rats from our own standard colony (Lehr, 1945, 1947). A condensation of the most important findings is presented in the accompanying tables and figures.

#### 1. Acute Toxicity

Table 1 illustrates the values for the acute toxicity. It demonstrates that combinations of sulphonamides are significantly less toxic than comparable or equal amounts of their individual constituents. Estimation on the basis of the toxicity

TABLE 1—Acute Toxicity of Sulphonamides given Single and in Various Combinations. (Single Intraperitoneal Injection of Sodium Salts in Albino Rats)

Drug	Dose (g./kg.)		No. of Animals	Deaths
	Partial	Total		
Sulphadiazine .. ..	1.5	1.5	60	80%
Sulphathiazole .. ..	1.1	1.1	24	65%
Sulphamerazine .. ..	1.3	1.3	31	65%
Sulphapyridine .. ..	1.1	1.1	34	65%
Sulphapyrazine .. ..	1.3	1.3	17	77%

figures of the separate compounds would give, for example, an expected toxicity of about 77% for the sulphathiazole-sulphadiazine mixture, about 68% for the sulphamerazine-sulphadiazine combination, and about 74% for the mixture of sulphadiazine and sulphapyridine, whereas the actual values derived from experimental results were only 12%, 37%, and 0, respectively.

\*Read at the Seventeenth International Physiological Congress in Oxford, on July 23, 1947.

†This investigation has been aided by grants from the Josiah Macy Jr. Foundation, New York City, and the Schering Corporation, Bloomfield, N.J.

Mixtures of three sulphonamides proved completely non-toxic at the 1.5 g. per kg. total dose level. This remarkably low toxicity pointed to a further increase in the protection afforded to the kidney against blockage with sulphonamide crystals.

Evidence of the presence or absence of renal obstruction was obtained from post-mortem examinations of the kidneys. Various degrees of kidney block caused by deposits of sulphonamide crystals in the renal tubules were observed in all animals succumbing to treatment with any of the five sulphonamides given singly. The kidneys appeared greatly enlarged and oedematous, and contained crystalline plugs in the papillary ducts, which in severe cases fanned out into the cortex. These drug deposits were clearly visible to the naked eye and easily demonstrable under the microscope. Rats treated with mixtures of three sulphonamides showed complete absence of renal blockage, and hence had normal kidneys. The lack of renal obstruction could also be inferred from normal non-protein nitrogen levels in the blood and high urinary elimination figures of sulphonamide. Added proof was derived from accurate chemical determinations of the sulphonamide amounts in the kidneys at various intervals after intraperitoneal injection of single and mixed sulphonamides.

Fig. 2 summarizes one representative experiment with animal groups killed 24 hours after intraperitoneal injection of sulphadiazine, sulphathiazole, sulphamerazine, and their combination

FIG. 2.—Findings in blood and kidneys of albino rats 24 hours after intraperitoneal injection of sulphadiazine (SD), sulphathiazole (ST), and sulphamerazine (SMD), given singly and in combination.

in the dosages used in the acute toxicity study. It indicates that rats injected with sulphadiazine showed the greatest discrepancy between blood and renal concentration of sulphonamide. The excessive concentration of sulphadiazine in the kidney is readily explainable on the basis of the massive crystalline deposition observed in this organ. The findings were similar although less marked in the sulphathiazole group. However, in this instance the large amount of conjugated sulphathiazole in the kidneys was of particular importance since the acetylated product has a solubility of only 7 mg. per 100 ml. at body temperature. Sulphamerazine caused the least intratubular precipitation, but showed the greatest tendency to the formation of gravel and concretions in the renal pelvis and ureters.

The mixture of all three sulphonamides did not produce any concretion formation in the urinary tract, and hence also did not reveal any difference between the concentration of sulphonamide in the blood and in the kidneys. It seems highly significant that the blood level of free sulphonamide resulting from the non-toxic dose of the mixture was actually higher than the levels obtained with comparable though fatal dosages of any one of the three mixture components under the conditions of renal impairment.

## 2. Subacute and Chronic Toxicity

The results of studies on the subacute toxicity are summarized in Table II. The daily dose of sulphonamides used was 0.9 g. per kg. In the mixture groups it consisted of equal amounts of the two or three compounds. The mortality figures shown

TABLE II.—Subacute Toxicity of Sulphonamides given Singly and in Various Combinations. (Intraperitoneal Injection of Sodium Salts for 5 Consecutive Days in Albino Rats)

Sulphamerazine .. ..	0.3	0.9	10	0
Sulphapyridine .. ..	0.3	0.9	10	0

are those observed on the sixth day of the experiment. The strikingly low toxicity of combinations as compared with the high mortality from separate compounds is immediately apparent. It should be mentioned, for the sake of completeness, that studies were also carried out with various mixtures containing sulphacetamide (N-acetylsulphanilamide), a sulphonamide of relatively high solubility. They proved, as expected, that the toxicity of such combinations was particularly low.

The results of the acute and subacute studies were confirmed in part also in chronic feeding experiments with weanling albino rats, although in tests based on voluntary drug intake the results are of necessity less clear-cut. On the one hand the taste of the standard food seems to be spoiled by certain sulphonamides (sulphathiazole, sulphamerazine) and not by others (sulphadiazine), which results in great differences in the food intake. On the other hand, tolerable amounts ingested over a long period of time may be insufficient to produce fatal renal complications but high enough to result in serious reactions due to the tissue toxicity of the sulphonamides. Hence, for comparative investigations of the renal toxicity of sulphonamides and their mixtures the incorporation of the drugs into standard food for voluntary consumption is not a good procedure.

## 3. Absorption-Excretion

The comparative absorption from the peritoneal cavity is exemplified for three combinations with the dosages used in the evaluation of acute toxicity. Fig. 3 shows that the blood levels from the sulphathiazole-sulphadiazine mixture are at all times almost as high as from sulphadiazine alone, despite the low toxicity of this combination. The urine volumes in an unimpeded flow of urine in the rats treated with mixture; this group consequently also reveals by far highest values for urinary drug excretion.

In a similar manner Fig. 4 demonstrates that the levels and particularly the urine concentrations of the sulphamerazine-sulphadiazine combination are higher than expected on the basis of the values from the individual compounds; is evident, in addition, from the columns representing urinary elimination of the drugs (in this instance on a cumulative basis) that excretion of the mixture is far more complete than from either compound administered singly in the amounts.

Fig. 5 illustrates the absorption and excretion of the mixture of three compounds. If compared with the previous two figures it is apparent that this sulphonamide combination gives excellent blood and urine concentrations. The total urinary elimination of sulphonamides is not only higher than from any one of the three compounds administered singly, but also significantly more complete than from a mixture of two. The behaviour of sulphonamide mixtures was observed also at small dosages and from other routes of administration.

The fate of sulphonamides and their combinations after administration of sublethal amounts is depicted in a representative experiment with the sodium salts of sulphadiazine and

FIG. 3.—The absorption and excretion of sulphadiazine, sulphathiazole, and their combination in albino rats after intraperitoneal injection of single dosages. All figures represent the mean of the values of 10 animals.

sulphathiazole. Fig. 6 illustrates the absorption and excretion after intubation of 1 g. of the mixture per kg. of body weight as compared with the same weight amounts of the separate compounds. It is apparent from the graph that the mixture gives the highest blood levels, initially also the highest urine levels, and again by far the most complete urinary excretion, indicating that a combination of half dosages is more fully utilized than the same amount of either sulphadiazine or sulphathiazole.

The explanation for the more complete absorption and elimination of sulphonamide combinations emerged from tests

FIG. 4.—The absorption and excretion of sulphadiazine, sulphamerazine, and their combination in albino rats after intraperitoneal injection of single dosages. All figures represent the mean of the values of 10 animals.

with single drugs in the partial dosages contained in the mixture. These studies proved that smaller amounts are more completely absorbed from the gut, and consequently also more completely eliminated by the kidney. This behaviour remained apparently unchanged even if two sulphonamides were administered simultaneously. Hence, with regard to absorption and excretion, the body seems to handle a combination of sulphonamides as if each of its constituents were present alone and in the partial dosage contained in the mixture.

Table III illustrates this general principle in the renal excretion figures for the sulphathiazole-sulphadiazine mixture as

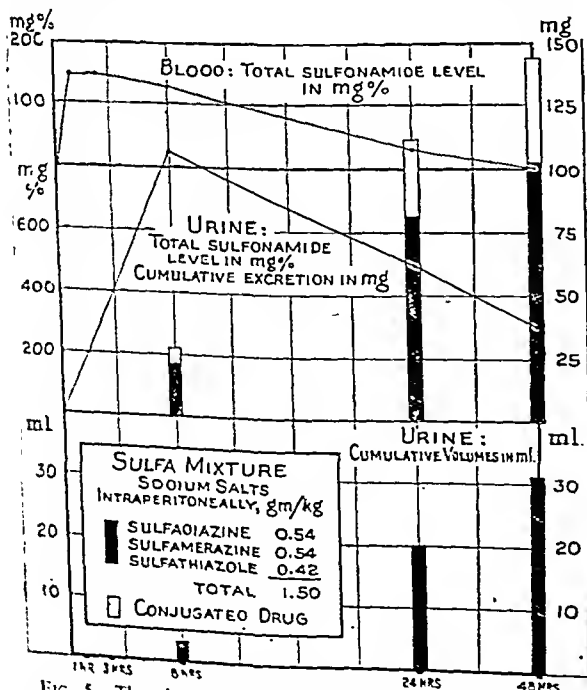

FIG. 5.—The absorption and excretion of a mixture containing partial dosages of sulphadiazine, sulphamerazine, and sulphathiazole after intraperitoneal injection of a single dose. All figures represent the mean of the values of 10 animals.

FIG. 6.—The absorption and excretion of sulphadiazine, sulphathiazole, and their combination after a single oral intubation. All figures represent the mean of the values of 10 animals.

contrasted with the values for the single compounds in equal and half dosages (Fig. 6). It is clearly apparent that the percentage of urinary excretion is strikingly higher from half

TABLE III.—*The Renal Elimination after 24 Hours of Sulphadiazine and Sulphathiazole, given Singly and in Combination. (Administration of Sodium Salts by Stomach Tube to Groups of 10 Albino Rats)*

Drug	Amount in g./kg. Body Weight		Amount of Dose Excreted

dosages, whether given singly or in combinations. Incidentally, the observations in the laboratory animal that sulphonamide mixtures give good therapeutic blood and urine levels were fully confirmed in absorption-excretion studies in man.

### Results of In-vitro Antibacterial Activity of Sulphonamide Mixtures

The main result of *in-vitro* experiments on antibacterial activity of sulphonamide mixtures was the observation that the action of similarly effective sulphonamides in combinations corresponds largely to the total content of sulphonamide; in other words, in mixtures of different but similarly effective sulphonamides the bacteriostatic effect is generally additive. True potentiation of action was observed in some instances (Lehr, 1945).

It should be kept in mind, however, that these results were obtained with equal sulphonamide concentrations in the test-tube, whereas the administration of equal dosages of the different sulphonamides and their combinations would result in significant differences in the drug concentrations in blood and tissues. In accordance with the results of the absorption-excretion studies, mixtures give excellent tissue levels; hence they should prove *in vivo* at least of the same, if not of higher, antibacterial value if compared with equal dosages of any one of their individual components. This point of view was well supported by clinical results.

### Results of the Therapeutic Use of Sulphonamide Combinations

Up to the present a total of more than 700 unselected patients with systemic infections have been treated at the Flower and Fifth Avenue Hospitals and at the Metropolitan Hospital in New York City with a mixture containing equal amounts of sulphathiazole and sulphadiazine, or sulphadiazine and sulphamerazine, on a routine dosage schedule (Lehr, 1946; Lehr *et al.*, 1946). The oral route was used in the majority of cases. In children the sulphadiazine-sulphamerazine combination was also given by the intravenous route. These results will be published later. Adequate fluid intake was assured, but no alkalizing agents were employed.

The therapeutic response to both sulphonamide combinations was highly satisfactory in most instances. Defervescence and general clinical improvement seemed to occur with greater speed when compared with previous experience with any of the drugs administered separately. Hence the total amount of sulphonamide used was comparatively small. Therapeutically effective blood levels (5 to 20 mg. free sulphonamide per 100 ml.) were maintained with ease. Urinary concentrations of sulphonamide varied between 100 and 600 mg. per 100 ml. Conjugation figures were as a rule low, ranging between 3 and 20%

of the total level in the blood, and 10 and 40% of the total amount in the urine.

Crystalluria was infrequent, and never of the "massive" type observed so commonly during therapy with single compounds. Of more than 900 acid morning specimens of urine containing sulphonamide mixtures, which were examined under the microscope after sharp centrifugation only about 7% were found to hold moderate or small amounts of sulphonamide crystals, as contrasted with the incidence of crystalluria of 29% from sulphadiazine, 26% from sulphamerazine, and 70% from sulphathiazole alone (Flippin *et al.*, 1941; Flippin and Reinhold, 1946). None of the patients treated with mixtures developed any sign of serious renal irritation. Quite unexpectedly the incidence of allergic reactions also seemed to have decreased. Nausea and vomiting were rare. No other toxic reactions were encountered. At present we are engaged in clinical studies with various mixtures of three sulphonamides.

Confirmation of these investigations came recently from several sources. Whitehead (1946), at the University of Colorado, confirmed the animal experimental data. Flippin and Reinhold (1946), at the University of Pennsylvania, extended the clinical observations. They showed in a well-controlled study that "the use of sulphadiazine and sulphamerazine in mixtures containing equal parts of each drug led to a considerably decreased incidence of crystalluria compared with that observed when either compound was administered singly." They concluded that for the prevention of crystalluria the use of the mixture was as effective as the administration of sodium bicarbonate at the rate of 12 g. a day with either sulphadiazine or sulphamerazine. Finally, Hagerman and his co-workers (Frisk *et al.*, 1946, 1947), in Sweden, using a combination of sulphathiazole, sulphadiazine, and sulphamerazine, arrived independently at confirmatory animal-experimental and clinical results.

### Summary

A new and simple approach to the prevention of renal complications from sulphonamide therapy is presented. It consists in the use of a mixture of several sulphonamides in partial dosages instead of single compounds. In solution each sulphonamide component of the mixture behaves as if present alone, exerting no influence on the solubility of the others. Consequently the danger of drug precipitation in the kidney was significantly decreased with sulphonamide mixtures, as shown in animal experimental and clinical studies. Actually it was only as great as if each compound had been given alone and in the partial dosage contained in the combination. On the other hand the chemotherapeutic effect of these mixtures was roughly proportional to their total sulphonamide content.

The results of these studies indicate that combinations of two or more sulphonamides should be used in preference to single compounds for all indications, since they combine a high therapeutic efficacy with a remarkably low renal toxicity.

The principle of dissolving several structurally similar and therapeutically equivalent drugs in the same medium to the full extent of the separate saturation levels for each compound might prove of value in any instance where sparingly soluble drugs have to be incorporated into small volumes of solvent.

## SULPHAMERAZINE TREATMENT OF PNEUMONIA IN ADULTS

BY

HORACE JOULES, M.D., F.R.C.P.

AND

S. D. V. WELLER, M.D., M.R.C.P.

(From the Central Middlesex County Hospital)

Pneumonia lost many of its terrors with the discovery and development of the sulphonamides, and the results of treatment of this disease are progressively improving. There is, however, a tendency to regard the sulphonamide drugs as superseded by penicillin not only in the severely ill but even in mild conditions where the former have proved adequate. Needles are never pleasant to the patient or convenient to the attendant. We hope to show that sulphonamide treatment for primary pneumonia in adults is satisfactory in the vast majority of cases, and should be given before confirmation of a clinical diagnosis, in the form of bacteriological and radiological reports, is available. Further, we feel that all but the most severe cases in aged or debilitated patients are reduced by this treatment to a two-day fever which can be adequately treated at home. Hospital care, with facilities for fuller investigation and treatment, is needed only for patients who fail to respond rapidly to sulphonamides or who are critically ill or whose condition is otherwise complicated.

Pneumonia commonly occurs without the classical physical signs. We maintain that, in the absence of an influenza epidemic, patients complaining of respiratory symptoms are suffering from some measure of lung consolidation if they have a temperature higher than 100° F. (37.8° C.) for more than one day. We have encountered many such patients in whom skiagrams have shown segmental or central consolidation, and we consider that in these cases should be given the benefit of a full course of a suitable sulphonamide without delay.

It is very desirable to obtain at the outset, and before treatment is started, a specimen of sputum for complete bacteriological investigation. This will give a reliable indication of the causal organism in 70% of cases. Radiological confirmation that resolution is complete, particularly in every patient over 40, is essential. Patients with carcinoma of the bronchus not infrequently present with pneumonia, but complete clearing rarely occurs.

### Sulphamerazine

We do not attempt to prove that any sulphonamide is more successful than penicillin in the treatment of pneumonia (although we have reached this conclusion from a small series of cases that are not statistically significant). Sulphonamide therapy is certainly less troublesome, and with the newer preparations there is no need for frequent dosage, with consequent loss of sleep. Toxic effects are minimal. In this hospital patients may be admitted to any medical ward under the care of any of the physicians, so that treatment is that considered best by the physician concerned and is in no way standardized. By common consent, however, the treatment now used almost invariably is that with sulphamerazine.

Workers in America have compared the pharmacological properties of sulphamerazine with those of other sulphonamides (Hageman *et al.*, 1943; Schmidt *et al.*, 1944b), while its toxic effects have been compared with those of sulphadiazine by Dowling *et al.* (1944) and with those of sulphamerazine by Schmidt, Hughes, *et al.* (1944a). Reviews and clinical evaluations of the use of sulphamerazine in pneu-

monia have been published by Genecin and Nelson (1945), Heffner (1945), and Volini *et al.* (1945).

Sulphamerazine, a methyl homologue of sulphadiazine, is absorbed more rapidly and excreted more slowly than sulphadiazine. At equal blood levels it is no more toxic than sulphadiazine and is far less so than many of the older preparations. As a result, a single dose of sulphamerazine will produce a higher blood level of the drug, and more quickly, than the same dose of sulphadiazine, and this blood level will be longer maintained (Flippin, Reinold, and Geftter, 1943; *Medical Uses of Sulphonamides*, H.M.S.O., 1945; *Lancet*, 1943). Being more soluble than sulphadiazine it presents less risk of urinary obstruction with crystals (Anderson, Oliver, and Keefer, 1944). The rapid absorption renders parenteral administration almost unnecessary, since an oral dose will produce therapeutic blood levels in two hours, while within four hours the blood levels remain the same as those obtained by equal intravenous dosage (Murphy, Clark, and Flippin, 1943). Thus in comparison with older sulphonamides smaller doses of sulphamerazine less frequently given will produce and maintain an adequate blood level (12-15 mg. per 100 ml. of blood). The course we have found satisfactory consists of an initial "loading" dose of 3 g., followed in eight hours by 2 g. and then 1 g. eight-hourly. The doses can be arranged so that patient and attendant can have an uninterrupted night. With this regime a blood level of 15 mg. is reached within four hours (Welch, Mattis, Latven, Benson, and Shiels, 1943). We have found that this level is well maintained throughout treatment. Adequate urinary output must be maintained by giving six pints (3.4 litres) of fluid daily, but alkali is not required, since it decreases tubular reabsorption of the drug and therefore increases its loss by excretion.

In our experience the above dosage is always well tolerated and rapid subjective improvement occurs. The temperature falls to normal in 24 to 36 hours in most cases and never rises more than 1° F. above normal afterwards. Treatment is continued, according to the severity of the case, for 48 to 72 hours after the temperature has reached normal, so that a moderately severe case will need about five days' treatment (18 g. in all). We found no evidence that such a dosage produced a reduction in granulocytes in the blood that could be attributed to the drug. This agrees with the findings of others, using somewhat larger doses (Flippin, Geftter, Domm, and Clark, 1943). Most patients are fit to get up after a week and leave hospital between the tenth and the fourteenth day from admission. Breathing exercises from the day after the temperature has fallen accelerate the disappearance of added sounds in the lungs. Fig. 1 graphically represents the progress of a typical case.

In addition to specific drug therapy we find that adequate sleep on the first night of treatment is best obtained with an injection of 1/4 gr. (16 mg.) of morphine, which also suppresses the painful cough; in older subjects pethidine, 100 mg. by injection, is adequate and in many ways preferable. A linctus for the first two or three days may be helpful to control the cough; a really effective preparation, such as linctus heroin, should be used. Alternatively, 1/12 gr. (5.4 mg.) or 1/6 gr. (11 mg.) of "dicodid," by mouth, is satisfactory. Pleural pain rarely persists long after the start of sulphamerazine, and is well relieved by spraying the chest wall with ethyl chloride; the relief lasts about three hours, and the spray may then be repeated if necessary. We have never resorted to strapping the chest.

Although the illness is shorter and less severe as a result of treatment, full convalescence is essential, since pneumonia affects predominantly those subject to the stresses

of overwork and the risks of overcrowding, and rarely strikes the healthy adult. The patient should be advised to see that his future life is modified so as to avoid a recurrence of those circumstances that rendered him an easier victim to pneumonia. This may mean that a housewife must be advised not to add to her burden by long hours in a factory and the enthusiastic gardener warned against over-indulgence in his hobby.

We have found that a small spike of temperature, up to but rarely exceeding 99.4° F. (37.4° C.), occurs in many cases. This spike was seen in 60% of our successfully treated cases, being found more often where a four-hourly temperature chart was maintained than where the temperature was taken twice daily. The spike occurred most frequently about thirty-six hours after the temperature had settled, and some cases showed two or more such spikes. In no instance was this phenomenon correlated with any

FIG. 1.—Chart of a typical case of severe lobar pneumonia treated with sulphamerazine.

failure of treatment or the development of any complication. It is met with as often in patients under penicillin as under sulphonamide therapy, and we have come to the conclusion that it need cause no misgiving.

**Present Series**

For this investigation the last 189 proved cases of pneumonia were studied—that is, those occurring since sulphamerazine became easily available. Criteria of diagnosis are clinical signs, supported by radiological evidence of well-defined consolidation, together with (in most cases) the presence of leucocytosis and the isolation of a causal micro-organism. Cases in which the pneumonia occurred as a terminal event in another mortal illness are excluded. In the series there were 101 males and 88 females. The average age for males was 43.0 years and for females 40.5 years, the extremes of age being 13 and 76 years.

Of these 189, 113 were treated with sulphamerazine from the start without a single death; 36 were treated with sulphamezathine (sulphadimethylpyrimidine), with three deaths; and 22 with penicillin, with one death. Combined

treatment was given to 12 patients, one of whom died. remaining cases were so mild that no specific therapy deemed necessary. The details of those dying in the series are:

- Treated with Sulphamezathine Alone (36 cases, 3 deaths)**
1. Man aged 52.—Chronic bronchitis for seven years. His indefinite. Died within two hours of admission. Diagnosis at necropsy: left lower-lobe pneumonia.
  2. Man aged 65.—An alcoholic polycythaemic patient. Indefinite chest illness for one month. Severe symptoms for three days. Died within 24 hours of admission. Diagnosis at necropsy: right mid-lobe pneumonia.
  3. Woman aged 66.—A known case of aortic stenosis. Complicating right lower-lobe pneumonia. Collapsed three days before admission after nursing dying husband. Severely ill. No response to treatment. Diagnosis confirmed at necropsy.

- Treated with Penicillin Alone (22 cases, 1 death)**
4. Man aged 59.—Admitted with acute pulmonary oedema. Died within 12 hours of admission. Diagnosis at necropsy: rheumatic aortic stenosis, acute pulmonary oedema, left-sid pneumonia.

- Treated with Combined Therapy (12 cases, 1 death)**
5. Girl aged 15.—Died 12 hours after admission. Left lower-lobe pneumonia complicating rheumatic mitral stenosis and aortic regurgitation, associated with acute pulmonary oedema. Confirmed at post-mortem examination.

It will be seen that no therapy could offer much, if a chance of recovery.

**The Sulphamerazine Group**

The sulphamerazine cases are considered in further detail. Three of the 113 were given sulphamerazine together with penicillin from the outset; one was critically ill, another less severely ill but rather old (66), and the third a case of moderate severity in a soldier, who would probably have responded well to either treatment alone. Among the remaining 110 patients the condition was classified as mild, moderate, or severe, according to the clinical impression. The age distribution, in decades, of these 110 patients recorded in the following table.

Age Period	No. of Cases	Age Period	No. of Cases
13-20 ..	11	51-60 ..	17
21-30 ..	22	61-70 ..	11
31-40 ..	25	Over 70 ..	3
41-50 ..	21		

**Bacteriology**

The sputa of 87 cases, in all groups of severity, were examined on admission, and 60 of these yielded on culture a causal micro-organism. The examination thus gave a positive finding in 70%. The pneumococcus was cultured in 53 cases, a haemolytic streptococcus in 10 cases (several times we encountered both organisms); Friedländer bacillus in 1 case, and *Staph. aureus* in 3 cases. Of the 27 cases which grew no pathogenic organisms the majority responded to treatment as if they had been pneumococcal in aetiology. Most cultures grew non-pathogenic organisms in addition, most frequently *Neisseria catarrhalis* and *Str. viridans*—the latter rarely in free or pure growth. This finding emphasizes the fact that to be of most value the examination must be carried out on a specimen of re sputum from the lung, and not saliva. In young and non-smoking subjects a specimen may be unobtainable.

**Results**

There were 17 mild cases in the series—9 men (average age 38) and 8 women (average age 37); thus these patients were, on the whole, young. Treatment of all but one was totally successful, fever disappearing in an average of 11 days and the patients leaving hospital in 11 days. The average dosage of sulphamerazine was 16.5 g. and the success rate 94%.

The moderately ill patients numbered 59 (31 men and 28 women), the average ages being 40 and 43 respectively. In 50 cases the results were totally successful, the temperature reaching normal in two days and discharge occurring in 15 days on the average. The dosage of drug used was 19 g. and the success rate 85%.

Of the 34 patients classified as severe cases the average age was 42 for both sexes, there being 21 men and 13 women. Sulphamerazine produced a successful response in 27, with the pyrexia settling in 2.2 days and discharge being given in 16 days after an average dosage of 19 g. The success rate here is 79%.

Thus, of 110 patients treated with sulphamerazine when a clinical diagnosis was made 93 gave a response regarded therapeutically as successful—an overall success rate of 84.5%. All cases were followed up in the out-patient department after convalescence if clearing was not demonstrated radiologically before discharge.

Among the successful cases there were 10 which developed small amounts of sterile pleural effusion, and 3 which had relapses of fever responding to a further course of sulphamerazine. Other minor complications were one temporary lobar collapse, one femoral thrombosis, and one abortion. In no case was convalescence seriously delayed.

#### Cases Given Additional Treatment

In 17 cases the response was deemed inadequate and further treatment was given. Fluid developed in 5 cases in amounts sufficient to justify aspiration. The fluid remained sterile throughout and no empyema occurred in the series. Parenteral penicillin was given to each.

Two cases developed lobar collapse, for which penicillin was administered to prevent a new infection becoming established in the collapse area. One severely ill woman developed a confusional psychosis after 7 g. of the drug, which was stopped and penicillin substituted. Her confusion cleared rapidly and she left hospital on the fifteenth day, her progress delayed neither by her psychosis nor by a small sterile effusion which developed. One moderately ill man with a pneumococcal infection developed a drug fever. After a tendency to early settling his temperature rose again and remained high throughout a course of 20 g. of sulphamerazine, falling critically thereafter, having almost reached normal before a three-day course of penicillin was started—probably unnecessarily.

Six patients seemed refractory to sulphonamides. Three yielded a growth of pneumococci on sputum culture, though the growth was not free, and—unfortunately in the light of events—the drug resistance of these strains was not tested *in vitro*. One case was mild and the temperature subsided by very slow lysis over four weeks, apparently unaffected by sulphamerazine (18 g.) or penicillin (three-hourly for 14 days). The other two (one moderate, one severe) responded promptly to penicillin after sulphamerazine had failed. Two other cases produced no pathogenic organisms from the sputum, and both were severely ill. One responded slowly and became afebrile on the eighth day of treatment, which consisted of sulphamerazine 20 g., producing a short-lived response, together with penicillin from the third to the tenth day. The other gradually improved over nine weeks regardless of treatment, his progress being punctuated by thrombophlebitis at three weeks and a lung abscess in the affected lobe at six weeks. These complications cleared completely by four months from the onset of his illness. The sixth case had 40 g. of sulphapyridine during 28 days before admission, and 18 g. of sulphamerazine resulted in no improvement, but the condition yielded dramatically to penicillin.

#### Staphylococcal Pneumonia

The remaining two cases were due to *Staph. aureus*. Certain strains of staphylococci are moderately sensitive to sulphamerazine. There were three cases of staphylococcal pneumonia in this series; one case, that of a man of 70, was among those successfully treated. His fever had already subsided when the laboratory reported a pure growth of *Staph. aureus* from his sputum; no relapse occurred after treatment. In the other two progress was not so smooth. The first became afebrile in 36 hours, so treatment was not changed on the bacteriological findings; a relapse followed the end of treatment, and this was promptly and finally dealt with by penicillin (60,000 units three-hourly for seven days). The second case seems typical of this condition, and is described in more detail; the temperature, pulse, and respirations are reproduced in Fig. 2.

A man, aged 34, who had been overworking, was seized at 3.30 p.m. on June 3, 1946, with severe left chest pain, breathing becoming difficult. He sweated profusely, vomited twice, and

FIG. 2.—Chart of a typical case of staphylococcal pneumonia treated with sulphamerazine and penicillin.

felt weak. He had a cough with scanty sputum. Examination showed signs of left basal consolidation when he was admitted the following afternoon. Sulphamerazine was administered in the usual dosage, and produced a reduction in pyrexia to 100° F. (37.8° C.) from the original 103.6° F. (39.8° C.). On the 7th the pneumonic process had extended to the left upper zone, and herpes labialis was present. When on June 9 the bacteriologist reported that staphylococci were present in the sputum penicillin was started. In 30 hours the temperature had dropped to normal, and progress thereafter was uneventful. (The picture in this case was confused by an early finding of pneumococci in the sputum; had this not occurred the case would have been recognized as staphylococcal-resistant to sulphonamide sooner than on the fifth day of treatment.)

#### Toxic Effects

One patient showed on the third day a transient rubelliform rash which faded in spite of further administration of sulphamerazine. In this case, unlike those described

by Hall and Spink (1943), there was no relapse of temperature with the eruption.

Two women became confused during treatment. One has already been mentioned; she had had only 7 g. and her treatment was changed to penicillin. The other developed a psychotic state only after an adequate course of treatment had been given; the confusion cleared in four days and the pneumonia resolved rapidly. Drug psychosis has been reported by Flippin, Gefter, Domm, and Clark (1943), but both these cases had small doses of sulphonamide, and their condition may have been due to pneumonia rather than its treatment.

Drug fever occurs with all sulphonamides. Gefter *et al.* (1943) reported it in severe cases, most of which had over 40 g. of sulphamerazine. Two cases occurred in this series, the pneumonia responding according to expectation but fever persisting unexplained until a critical fall after stopping the drug incriminated the sulphonamide.

We have encountered no serious toxic manifestations in the use of this sulphonamide, and feel that they should be excessively rare provided that administration is not too prolonged.

### Summary

A series of cases of primary pneumonia in adults is presented. No deaths occurred among 113 cases treated with sulphamerazine. Five deaths (7% mortality) occurred among 76 treated with other agents, including combined therapies. The total mortality was 3%.

It is claimed that sulphamerazine, which can be given in relatively small doses at eight-hourly intervals, is a satisfactory therapeutic agent for this disease. The results are such that pneumonia can be treated at home and be reduced to a "two-day fever." Should no response follow within 48 hours the case should be reviewed at once and the facilities provided by the hospital for further investigation and treatment be employed.

The need for radiological demonstration of complete resolution is emphasized, as is the need for adequate convalescence.

Dr. Samuel Standard, the Associate Professor of Clinical Surgery at New York University, "has found that powder-puffs are a menace to health," reports B.U.P. "Anyone who has seen a powder-puff pulled out of a lady's handbag containing loose change, tobacco dust, and handkerchiefs, clean or otherwise, must have looked in awe as the perspired face and forehead were punished by swift, firm, hasty strokes smeared on fiercely by a deft, practised hand. Twenty-four hours later the owner of the face is surprised to find a crop of pimples spread over the cheek and forehead. In despair, she covers these again and again by the same method, and her wonder grows that her pimples multiply."

## ORAL PENICILLIN IN TREATMENT OF PNEUMONIA IN THE ADULT

BY

T. ANDERSON, M.D.

AND

J. B. LANDSMAN, M.B.

(From the University of Glasgow and Knightswood Hospital)

A comparative study (Anderson and Ferguson, 1945) of the efficacy of the sulphonamides and penicillin in the treatment of pneumonia showed that there was little to choose between the two methods. Although certain advantages could be claimed for penicillin on account of its lack of toxicity, its use had one great drawback, especially for the general practitioner—the need for repeated intramuscular injections. Early studies with regard to the route of administration of penicillin had suggested that the material was likely to have little effect when given by mouth because of its inactivation by the acid of the gastric juice (Abraham *et al.*, 1941) or because of penicillinase production by coliform organisms (Chain and Florey, 1944). This led different workers to try to combine penicillin with suitable antacids and buffers designed to counteract the stomach acids (e.g., Little and Lumb, 1945). Bunn and his co-workers (1945) used penicillin orally in the treatment of 45 cases of pneumonia and had only one fatality. The material was given in a gelatin capsule in about half of the cases the capsule contained an oil suspension and in the remainder the ordinary powdered sodium salt was enclosed. However, Finland, Meads, and Ory (1945) came to the conclusion that elaborate buffering devices were unnecessary and that administration with saline or even water was equally valuable in procuring effective therapeutic blood levels. These authors obtained satisfactory results with oral penicillin in the treatment of seven cases of adult pneumonia. Bushby and Harkness (1946), who reviewed the conflicting reports on different methods of administration, used penicillin orally for the treatment of gonorrhoea and were satisfied with the results which indeed were as good as those obtained with intramuscular penicillin. (It is important to realize that these results were obtained in adults, for Buchanan (1946) has since shown that oral penicillin can be used with excellent effect in infants whose normal achlorhydria was assumed to prevent inactivation of the antibiotic.)

In view of the great variations in the sensitivity of different organisms to the action of penicillin and because of the differences in severity between cases of the same infection, it was felt that there was a need to investigate the efficacy of penicillin administered orally to an unselected series of patients with pneumonia. In this infection, unlike gonorrhoea, the treatment must be capable of dealing with the bacteria not only in the tissues but also in the blood stream; it seemed possible that penicillin given by mouth might be unable to attain concentrations in the blood high enough to quell a bacteraemia.

### Material and Methods

The patients comprised in the study were all adult males admitted to the wards of Knightswood Hospital during the winter of 1946-7 in whom the diagnosis of pneumonia was confirmed. They were divided into two groups, one group being given penicillin orally and the other penicillin intramuscularly as a control. There was no conscious selection of patients for either method; on admission they were allocated alternately to the two groups.

**Intramuscular Penicillin.**—The patients in this group were given an initial dose of 50,000 units, after which successive doses of 20,000 units were administered at four-hourly

intervals for a period of five days. Occasional severe cases received higher dosage in the early stages of treatment. The mean total dose of penicillin was 800,000 units.

**Oral Penicillin.**—Tablets of calcium penicillin with 0.5 g. of sodium citrate were used. They were made up to contain 20,000 and 25,000 units of penicillin, so that it was possible to vary the scheme of dosage. At first 40,000 units were given three-hourly, but it was soon apparent that this dose was too low, and thereafter for a considerable part of the trial the standard dose was 60,000 units three-hourly, at least during the early stage of treatment. Administration was continued for a period of five days. Towards the end of the trial further variations were made in the dosage, the principal one being that the three-hourly dose was reduced to 25,000 units after treatment had continued for 48 hours. The mean total dose given orally was 1,650,000 units. In order to avoid too much disturbance of the patient a double dose was given at midnight and the next dose at 6 a.m. Two measures were adopted in an endeavour to enhance absorption and to maintain effective blood levels: in the first place, the tablets were always administered along with a small amount (1–2 oz.: 28–56 ml.) of milk; and, secondly, the daily fluid intake was reduced to 2 pints (1.136 litres). Rather to our surprise this latter restriction was tolerated by the patients, and with adequate nursing supervision no difficulty was experienced in keeping the tongue moist and clean.

The bacteriological and clinical control was similar to that used in previous trials (Anderson and Ferguson, 1945). Pneumococcus typing from sputum was, however, somewhat restricted by the lack of adequate supplies of typing serum; the available supplies were kept for the examination of special cultures.

### Results

The two groups of cases showed a fairly similar composition. The age distribution, duration of illness, and the presence of bacteraemia are shown in Table I. It will

TABLE I.—Composition of the Two Treatment Groups

	Intramuscular Penicillin	Oral Penicillin
<b>Age distribution:</b>		
0–20 years .. .. .	0	3
21–40 " .. .. .	14	13
41–60 " .. .. .	22	18

<b>Total .. .. .</b>	<b>9</b>	<b>14</b>
<b>Duration of illness on admission:</b>		
0–2 days .. .. .	18	23
2–4 " .. .. .	13	13
5+ " .. .. .	14	9
<b>Mean duration (days) .. .. .</b>	<b>3.5</b>	<b>3.2</b>

be seen that in respect of the factors considered to have the greatest effect upon the prognosis there was little difference between the two groups. In so far as previous sulphonamide treatment was concerned routine estimations of the blood level on admission were not made during this trial. Of those who were given intramuscular penicillin 23 had received some sulphonamide before admission, but only seven had received more than 4 g. In the oral group the equivalent figures were 24 and 10, of whom two had received a single injection of penicillin intramuscularly.

The effect of treatment in the two groups has been compared in respect of the duration of fever, the occurrence of complications, and the number and causes of deaths. The average duration of fever in uncomplicated cases was: "intramuscular" group, 1.9 days; "oral" group, 1.4 days. A composite temperature chart (Fig. 1) shows little difference between the effect of the two methods of treatment.

FIG. 1.—Duration of pyrexia in uncomplicated cases of pneumonia treated with penicillin.

Complications developed in 12 of the patients given intramuscular penicillin and in 16 of those given oral treatment. The individual complications are listed in Table II. It shows that there is no appreciable difference between the two groups.

TABLE II.—Complications in the Two Treatment Groups

Complication	Intramuscular Penicillin	Oral Penicillin
Lung abscess .. .. .	2	0
Empyema .. .. .	1	1
Sterile effusion .. .. .	2	1
Delayed resolution .. .. .	7	13
Lobar collapse .. .. .	0	1

The patients who died are recorded in Table III, which includes relevant details regarding their clinical condition. Study of the table throws light on the present status of pneumonia therapy, for it is apparent that in many of the patients the presence of some accompanying disease or degeneration was a contributory factor which weighed too heavily against effective treatment. Thus in four of the patients other conditions were present which were of themselves sufficient to have produced a fatal issue. The mortality rate for the series is 7.8%, and when it is recalled that 20 of the patients were over the age of 60 years such a low rate may be regarded with satisfaction.

TABLE III.—Deaths

Case	Age	Method of Treatment	Duration of Illness Before Admission	Extent of Consolidation	Blood Culture	Complicating Factors	Cause of Death

L1 and L2 = Left upper and left lower lobe. The figure in parentheses under "Blood Culture" refers to the type of pneumococcus.  
\* Received sulphonamide treatment before admission.

Clinical details are given of two typical cases, one in the younger age group and the other, a particularly severe case, in the older age group.

### Case 1

Treatment: penicillin orally—60,000 units three-hourly for 54 hours, then 40,000 units for 75 hours: total 2,120,000 units (Fig. 2).

A man aged 27 was admitted on Dec. 11, 1946; temperature 102° F. (38.9° C.), pulse 120, and respirations 40. On Dec. 8 he had had a sudden attack of shivering, followed by severe

FIG. 2.—Chart of Case 1. Total penicillin, 2,120,000 units.

pain in the right chest anteriorly. Headache, troublesome cough, and rusty sputum were also noted. He had had several previous attacks of bronchitis. Sulphonamide had not been given before admission.

On admission the patient was acutely ill; his tongue was very dirty. Examination of the chest revealed a pneumonia involving the greater part of the right lung; this was later confirmed radiographically. Rales were numerous in both lungs, and there was a suggestion of spread of consolidation into the left lower lobe. The blood culture was sterile; sputum, pneumococcus Type II; W.B.C., 15,800 per c.mm. (polymorphs, 91%). Next day the temperature, pulse, and respirations fell and the patient's appearance improved, although there was no improvement in the chest signs. On the 15th, signs of consolidation were most pronounced in the middle third of the right lung. The general condition was much better. On the 23rd the chest was clear clinically and radiographically. The patient was discharged on Dec. 26.

### Case 2

Treatment: penicillin orally—60,000 units three-hourly for 54 hours, then 40,000 units three-hourly for 57 hours: total, 1,840,000 units (Fig. 3).

The patient, a man aged 54, was admitted on Feb. 11, 1947, his sixth day of illness, having collapsed while at work. He

complained of shivering, pain in the chest, cough, and sputum. He had had no previous illnesses, and no treatment had been given before admission. His temperature was 100° F. (37.8° C.), pulse 96, and respirations 28.

Physical examination showed a poorly nourished man who was acutely ill, cyanosed, and dyspnoeic. The tongue was red and coated. There were signs of consolidation in both lower lobes. A blood culture performed on admission proved to be positive, and Type V pneumococci were so numerous on 1 pour-plate as to be uncountable. The W.B.C. numbered 6,400 per c.mm. (polymorphs, 93%). Next day the physical signs in both lungs were unchanged, and the cyanosis and dyspnoea were not improved. Auricular fibrillation was now present. Recovery was slow and uneventful, except for an elevation

FIG. 3.—Chart of Case 2. Total penicillin, 1,840,000 units.

temperature to 100.8° F. (38.2° C.) on March 1. At this time there was excessive prominence of old varicosities on the right leg, with surrounding redness. This subsided after 48 hours' rest in bed. When discharged after 36 days in hospital the chest had cleared except for a little basal rale.

### Discussion

From the results recorded it is clear that the oral administration of penicillin is a satisfactory method of treatment for pneumonia. Our experience would suggest that treatment should start with a daily oral dosage equal to four times that required by the intramuscular route. After obvious clinical improvement (usually within 48-72 hours) this dose may be reduced by half. It is interesting that such a schedule is much smaller than that used by Bunn *et al.* (1945) and by Finland *et al.* (1945). When attention is directed solely to those patients who had bacteraemia at the beginning of treatment it may be noted that in nine of them the colony counts were between 4 and 624 organisms per ml. and that in two others the organisms were too numerous to count. The satisfactory recovery of seven of these cases (including one of the latter) is good evidence of the efficacy of the oral method of

presentation. With regard to the technique of administration it would seem desirable at present to give the antibiotic as we gave it—namely, in milk and with a maximum fluid intake of 2 pints a day.

The necessity for a larger dose of penicillin makes it apparent that destruction of the antibiotic must take place at some part of its course through the body. Even with this increased dosage high inhibition levels in the blood serum were not obtained and indeed inhibition was rarely found in dilutions of serum above 1 in 2. Whether the state of the stomach juices during an acute infection such as pneumonia is an important factor in diminishing the amount of destruction may be worth further examination. One of us (J. B. L., unpublished) has shown that there is a decided diminution in the hydrochloric acid content of the gastric juice in pneumonia, and that this hypochlorhydric or achlorhydric state does not disappear immediately upon clinical recovery. The significance of such a finding is not at once apparent, but it may be a contributory factor in preventing an excessive destruction of penicillin. It would seem of some importance to make test-meal studies in other acute infections to see if this loss of hydrochloric acid is a common feature.

It should perhaps be emphasized that the indications for penicillin therapy are not changed by the present report. The sulphonamides constitute an adequate method of treatment for the majority of cases, more especially in the younger age groups; but for those patients who require penicillin there may be some advantage in the use of the oral route. In the first place, the difficulties associated with continued injections are overcome and treatment of pneumonia with penicillin in the home becomes practicable. Secondly, it seems possible that therapy might be cheapened by the use of substandard penicillin, which would not require the careful sterilization and packing necessary when used by injection.

The tablets were supplied by Burroughs Wellcome, to whom we are indebted for the opportunity of conducting the trial. We wish to thank Dr. F. Prescott and Dr. G. Brownlee for their advice and help.

*Man Against Pain: The Epic of Anaesthesia* (By Howard Riley apcr. Victor Gollancz, Ltd. 1947. 10s. 6d.) can hardly be regarded as a serious contribution to the literature of the history of anaesthesia, for it is written for the lay public in a journalistic style. For example, in analgesia "the patient is woozy but not unconscious," and "avertin is administered per rectum in the form of a nice little pink enema." On the title page is the quotation: "If America had contributed nothing more to the stock of human apyness than anaesthetics, the world would owe her an everlasting debt of gratitude." The author develops this theme to such an extent that the British reader becomes rather irritated by his depreciation of much outstanding European work. For instance, the introduction of ether anaesthesia, together with an account of the controversy about Morton, Long, Wells, and Jackson, occupies 88 pages, while he dismisses Simpson's discovery of the anaesthetic properties of chloroform in just over one page. He ignores the pioneer work of British anaesthetists done during and after the 1914-18 war in evolving the inhalation technique of endotracheal anaesthesia and blind nasal intubation, yet fully describes the relatively trivial modification of using a cuffed tube instead of a sure pack in a chapter entitled "The Dunked Dog."

## ORAL PENICILLIN IN YOUNG CHILDREN

BY

A. I. SUCHETT-KAYE, M.D. Paris

AND

R. B. LATTER, M.B., Ch.B.(N.Z.), M.R.C.P.Lond.

(From St. Charles's Hospital, L.C.C.)

We report here a clinical trial in which we treated 25 children, originally diagnosed as suffering from pneumonia, with oral penicillin. It is hoped that our modest contribution will induce others to try out on a bigger scale the oral administration of penicillin in sick children. No references to systematic experiments in the treatment of pneumonia in young children with oral penicillin could be found in the literature, and therefore the instructions given, especially those regarding the dosage, had to be modified after experience had been gained from the first few cases.

The original instructions given were as follows: (a) Pharyngeal swabs to be taken before treatment, and the isolated organisms to be tested for penicillin sensitivity. (b) The chest to be x-rayed as soon as possible after admission and again at the completion of treatment. (c) A record of the fluid intake to be kept; no extra fluids to be given unless specially ordered. (d) Oral penicillin to be given 4-hourly (later modified to 3-hourly) except for the last night dose, which may be doubled if a prolonged uninterrupted sleep is desirable. Dosage: Infants up to 6 months, 10,000 units (later increased to 20,000 units); between 6 months and 1 year, 20,000 units (later increased to 30,000 units); over 1 year and under 2, 30,000 units (later increased to 40,000 units). The treatment was continued for five days or less according to progress made by the child. Each tablet contained calcium penicillin 20,000 i.u. and sodium citrate 0.5 g. One or more tablets were crushed in water or milk and given preferably before feeds.

The dosage was originally calculated according to body weight in the proportion of 50,000 units per 24 hours for a 14-lb. (6.3-kg.) baby—say 8,000 units 4-hourly day and night. This dosage was based on that of 500,000 units per 24 hours for a 10-stone (63-kg.) adult, an amount of oral penicillin apparently effective against pneumonia in the adult (Prescott, 1947, personal communication). Buchanan (1946) considered 4,000 units per lb. (0.45 kg.) of expected body weight per 24 hours effective in young children. In the more severe cases, especially the later ones, and in view of the results of serum-penicillin estimations, these doses and sometimes larger ones were given at 3-hourly instead of 4-hourly intervals. At most oral penicillin was given for five days, and in several cases where clinical improvement was rapid the treatment was discontinued earlier than the fifth day.

#### Clinical Results

Of the 25 children treated 2 were under 6 months old, 9 between 6 months and 1 year, and 14 between 1 and 2 years old. The revised clinical diagnosis in 18 cases was bronchopneumonia, in 5 lobar pneumonia, and in 1 bronchitis. The remaining child developed measles the day after admission; treatment was stopped and she was removed to a fever hospital. The five cases of lobar pneumonia and 11 cases of bronchopneumonia were considered seriously ill on admission. In 15 cases the diagnosis was confirmed by radiography. Most of the children had a history of one to three days' illness before admission, but 2 had been ill for as long as seven days. In most of the cases pneumococci and streptococci (principally

*Str. viridans*) were isolated from the upper respiratory tract; all these organisms proved to be penicillin-sensitive.

Four children failed to complete the course of treatment because they were sent on the third or fourth day to fever hospitals: one with acute meningitis and three with gastro-enteritis. All showed marked improvement of general and chest condition. They comprised the two children under 6 months and two in the group of those aged 1-2 years.

Four other children, who were gravely ill and failed to show any clinical improvement on oral penicillin after three or four days, were given sulphamezathine and recovered (see Table I). In two of these cases there is no record of what organisms were grown from the pharyngeal swabs; in one the predominant organisms were reported to be penicillin-sensitive, in the other penicillin-resistant.

TABLE I.—*Diagnosis and Treatment*

No. of Cases	Diagnosis	Oral Penicillin	Sulphonamides	Penicillin Course Not Completed
18	Bronchopneumonia	11	4	3
5	Lobar pneumonia	4		1
1	Bronchitis	1		

The 25th child developed measles the day after admission and is not included in the table.

The other children all had normal temperatures within 2-4 days and recovered uneventfully except for one infant, who has bronchiectasis and is still in hospital after three months. The average stay in hospital, apart from that spent by this child, those transferred to fever hospitals, and one taken home against advice on the tenth day, was 19 days, the shortest being seven days and the longest 35.

#### Serum-penicillin Levels

Estimations of serum-penicillin levels after oral administration of single doses of penicillin were made by the method described by Fleming and Smith (1947), who used a mixture of glucose, phenol red, and serum water as the culture medium and a streptococcus as test organism.

TABLE II.—*Serum-penicillin Levels*

Case No.	Age in Months	Dose in Units	Serum-penicillin Level (i.u./c.mm.) at Hours after Administration						
			½ hr.	1 hr.	1½ hr.	2 hr.	2½ hr.	3 hr.	4 hr.
1	7 months	20,000	0.25			0.06			
2	3 "	10,000	0.03	0.25		0.03			
3	23 "	30,000		0.25		0.03			
4	14 weeks	10,000

The mark — indicates no inhibition with standard streptococci.  
The blood samples from Case 4 were stored for three days before testing and no penicillin could be detected. The blood samples from Case 5 were kept by mistake in the incubator for 24 hours and no penicillin could be detected.

#### Toxic Manifestations

Ellinger and Shattock (1946) reported a case of nicotinamide deficiency following administration of oral penicillin. They inferred that the nicotinamide deficiency was due to the effect of penicillin on the intestinal flora. Bushby and Harkness (1946), in a series of 85 adults, reported one case only of urticaria with oedema of hands, feet, and neck after oral penicillin.

Only one of our children developed, 10 days after completion of treatment, a blotchy urticarial rash. The temperature was slightly raised and diarrhoea was present. In another child, three days after treatment, a transient simple diarrhoea was noted. No pathogenic organisms were isolated from the stools of either case. Three other infants, transferred to fever hospitals, were diagnosed as having "gastro-enteritis"; their condition was excellent and the intestinal symptoms appeared on the third or fourth day during the course of oral penicillin. We think it possible that the diarrhoea in these cases was due to a direct toxic action of calcium penicillin on the digestive tract.

#### Comment

Oral penicillin appears to be effective against most varieties of acute pneumonia in childhood. Serum-penicillin estimations suggest that it should be. Some types of severe bronchopneumonia do not respond favourably, and for these parenteral penicillin and/or sulphonamides are the most efficacious. As György *et al.* (1946) rightly insist, for very sick children intramuscular penicillin is advisable, at least during the early acute phase of the disease. However, where circumstances are such that special nursing and frequent injections are impracticable, oral penicillin given in adequate doses at least 3-hourly will be of great benefit. If only for that alone the administration of oral penicillin is an important advance in chemotherapy.

#### Summary

Twenty-five young children were treated with oral penicillin. Of these 18 had bronchopneumonia, 5 lobar pneumonia, and 1 bronchitis; the remaining child was removed to a fever hospital with measles.

Of those with bronchopneumonia 11 made a satisfactory recovery on oral penicillin alone, 3 greatly improved but did not complete the course, and 4 failed to respond and were treated successfully with sulphonamides. Of those with lobar pneumonia 4 recovered on oral penicillin and 1, much improved, did not complete the treatment. One child with acute bronchitis recovered quickly in three days on oral penicillin.

In 21 children, all under the age of 2, serum-penicillin levels were estimated after a single oral dose varying from 10,000 to 40,000 i.u.; no penicillin was detected after three hours. The preparation used was calcium penicillin with sodium citrate.

Our thanks are due to Dr. E. A. Straker for performing the serum-penicillin estimations. We are indebted to Messrs. Burrol Wellcome and Co. for supplying the tablets of oral penicillin.

The Minister for Health has appointed a committee to examine the present system of medical education in Eire, and to recommend any necessary changes in the curriculum and in the arrangements for postgraduate education. The committee consists of: R. Farnan (chairman), Professors J. M. O'Connor, J. W. Bigger, W. O'Donovan, and S. Shea; F. Gill, president, Royal College of Surgeons in Ireland; B. Solomons, president, Royal College of Physicians of Ireland; J. C. Flood, Apothecaries' Hall of Ireland; A. A. McConnell, President, Royal Academy of Medicine in Ireland; A. Ryan, president, Medical Association of Eire; R. Atkins, Stoney, president, Medical Registration Council of Ireland; J. Saunders, Medical Superintendent Officer of Health, Cork; O'Hanrahan, County Surgeon, Roscommon; H. J. Moloney, S.C. P. C. Cahill, M. Rynne, Legal Adviser, Department of External Affairs; T. O. Raifeartaigh, Chief Inspector of Secondary Schools; Department of Education; J. A. Deeny, Chief Medical Adviser, Department of Health; and J. Kearney, Inspector of Mental Hospitals, Department of Health. Dr. J. A. O'Sullivan, Medical Inspector, Department of Health, has been appointed secretary to the committee.

## "LYMPHATIC REACTIONS" AMONG RELATIVES OF LEUKAEMIC PATIENTS

BY

S. N. ARDASHNIKOV

Department of Radiology, Molotov's Central Research Institute  
of Roentgenology and Radiology

In our first report (1934) we called attention to the extremely rare manifestation of the genotypical factors predisposing to leukaemia. This, taken together with a peculiar lymphatic reaction in a brother of a leukaemic patient, suggested the possibility of atypical cases, or "formes frustes," among the relatives of leukaemic patients. In fact, while leukaemia is not always manifest as such in bearers of the leukaemia genotypical factors, it might occasionally appear in some peculiar form of the disease. Some such cases of lymphatic reaction in members of a leukaemic family are described below.

### Case Records

**Case 1.**—In this family in 1898 a 7-year-old girl died from leukaemia, although of what type could not be determined at this late date. The subject investigated is her brother, a 25-year-old engineer. On March 22, 1931, he felt generally unwell and weak and had a slight fever. A few days later he had a sore throat, and tonsillitis was diagnosed. This disappeared after a few days, but the pyrexia remained until April 6, rising in the evenings to 38–39° C. (100.4–102.2° F.) and falling in the mornings to 37.5° C. (99.6° F.). The patient continued to complain of general malaise and weakness. A blood analysis done on April 3 showed: Haemoglobin, 82%; erythrocytes, 4,980,000; leucocytes, 18,100 (rod-nuclears ("Stab"), 2%, polynuclears, 2%; eosinophils, 1%; lymphoidocytes, 92%; lymphocytes, 3%).

With a diagnosis of "lymphatic leukaemia" the patient was directed on April 17 to the Central Institute of Haematology and Blood Transfusion for treatment. A blood analysis made on April 19 at the Institute showed no leucocytosis, though it did reveal a considerable lymphocytosis and an increase in young forms: Haemoglobin, 70%; erythrocytes, 4,095,000; leucocytes, 7,500 (rod-nuclears, 7%; polynuclears, 10%; lymphocytes, 80%; monocytes, 3%). No abnormalities could be found except slightly enlarged submaxillary lymphatic glands and liver. On April 22 the patient left the Institute with a diagnosis of "lymphatic reaction following tonsillitis." Towards the end of 1932 the patient's blood was again examined because he complained of general weakness and some malaise; the analysis showed "absolute lymphocytosis." Our examination of the patient in 1933 showed no abnormality.

The patient's grandmother died of a liver complaint. His father and mother—first cousins—are living and show no blood anomalies. The same is true of the patient's brothers and sister.

The subject was under our constant observation. In May, 1937, he again had tonsillitis. Not being informed of this in time, we were able to take blood for analysis only on the third day after his recovery. The analysis showed the following: Leucocytes, 17,400 (rod-nuclears, 5%; polynuclears, 57%; eosinophils, 15%; lymphocytes, 34%; monocytes, 3%; Türk cells, 1%). The leucocyte count was thus increased, but there was only slight lymphocytosis.

This is a case, therefore, of a man who is a member of a leukaemic family and who shows a peculiar lymphatic reaction expressing itself as an absolute lymphocytosis and leucocytosis during an infection of the throat a month after the symptoms of tonsillitis have disappeared, and even independently of any infection.

**Case 2.**—This case concerns a pair of identical girl twins. Twin A, 11 years old, entered the clinic on Sept. 29, 1936, with a diagnosis of acute rheumatic polyarthritis and diseased mitral valve.

The patient had pneumonia when 2 months old, German measles at 18 months, chicken-pox at 5 years, and at 6 years tonsillitis (possibly diphtheria) complicated by paralysis of the limbs and pains in the joints, the condition lasting about three months. Up to 6 years of age she often had attacks of false croup and "chills." When 8 years old she had paratyphoid fever, and at 12 measles. From early childhood up to 8 years of age she suffered from broncho-adenitis.

The following information was obtained from the patient herself and her mother, and was confirmed by reference to case records and the statements of her physician. On March 28, 1935, the patient suddenly became feverish, her temperature rising to 39.8° C. (103.6° F.). The temperature then rose at noon, in the evening, and sometimes in the morning. The liver and spleen were enlarged to almost double normal size. The cervical, axillary, and inguinal lymphatic glands were greatly enlarged. Blood examined for malaria parasites was negative. Blood analysis (April 7): Haemoglobin, 70%; erythrocytes, 4,100,000; leucocytes, 24,000 (rod-nuclears, 3%; polynuclears, 2%; lymphocytes, 93%; monocytes, 1%; Türk cells, 1%); polychromasia was seen. The analysis thus revealed that the patient had considerable leucocytosis and marked lymphocytosis. A later analysis confirmed these findings.

After a week's time the patient's temperature fell to 37.3° C. (99.2° F.), but on April 10 symptoms of tonsillitis appeared—complaint of sore throat, small patches of membrane, reddened pharynx—and bacteriological examination revealed the presence of streptococci. Two or three days later the temperature returned to normal. Liver, spleen, and glands decreased in size. Blood analysis made on April 18 showed decreased leucocytosis but still considerable lymphocytosis: Haemoglobin, 72%; erythrocytes, 3,980,000; leucocytes, 7,000 (polynuclears, 28%; eosinophils, 1%; lymphocytes, 65%; monocytes, 6%).

In view of the still abnormal blood picture the patient was directed to the children's clinic of the First Moscow Medical Institute to have the diagnosis checked. According to the case-history records all lymphatic glands were enlarged, the spleen was palpable at the costal margin, and the liver was enlarged 2.5 cm. Though numerous blood analyses were made, the number of leucocytes were never found to be above 6,000–7,000. Lymphocytes remained constantly at 70–80%. In July, 1935, the patient left the clinic with the diagnosis of "lymphatic reaction following tonsillitis." Shortly afterwards petechiae appeared on the patient's body and disappeared after a few days. There was no rise of temperature and no enlargement of the glands. The patient was under observation for a year by the Central Institute of Haematology and Blood Transfusion. Data from the subject's blood analyses after she left the clinic of the First Moscow Medical Institute, obtained between June 26, 1935, and April 13, 1936, are presented in Table I.

TABLE I

Date of Analysis	Hb %	Erythrocytes	Leucocytes	Rod-nuclears	Polynuclears	Eosinophils	Basophils	Lymphocytes	Monocytes
April 26, 1935 ..	64	3,880,000	4,800	3	40	5	—	46	2
July 13, 1935 ..	70	4,320,000	6,000	—	43	2	—	52	3
Sept. 8, 1935 ..	70	3,650,000	7,800	—	52	4	—	38	6
Sept. 23, 1935 ..	63	4,010,000	7,400	0.5	31.5	2	—	60.5	5.5
Oct. 24, 1935 ..	63	4,010,000	6,700	—	—	—	—	60	—
Nov. 29, 1935 ..	64	4,200,000	4,600	0.5	56.5	3	—	36	4
Dec. 25, 1935 ..	58	3,600,000	6,800	0.5	27	1.5	0.5	68	2.5
April 13, 1936 ..	50	4,420,000	4,400	0.5	19	5	—	70.5	5

As the table shows, while the leucocyte count is normal or only slightly increased, there is a definite tendency towards increase in the lymphocyte count, and this, despite the long period of time elapsed (over a year) since the increase started.

From July 4 to 8, 1936, the patient was ill with colitis (? dysentery). The temperature rose to 39.6° C. (103.3° F.). After the colitis the patient complained of pain in both knee-joints; there was no swelling or redness, and the temperature remained normal. The pains went within four days. A month later symptoms of colitis recurred. Temperature rose to

37.8° C. (100° F.). After a week the colitis and pyrexia disappeared. On the morning of Sept. 11 the patient vomited, became somnolent, but was not feverish. A blood analysis made at this time showed: Haemoglobin, 60%; erythrocytes, 3,800,000; leucocytes, 10,000 (rod-nuclears, 3%; polynuclears, 55%; eosinophils, 2%; lymphocytes, 30%; monocytes, 10%); sedimentation rate, 30 mm. per hour.

On Sept. 12 the right knee-joint became swollen and painful, the temperature remaining normal. The next day the same condition occurred in the left knee-joint. Several days later both ankles became slightly swollen, and the temperature rose in the evenings to 38.2° C. (100.8° F.). During one of the attacks of pain in the joints the patient's body began to jerk all over; the convulsive movements ceased when bromides were given. In this condition the patient entered the clinic. Clinical examination confirmed findings typical for rheumatic polyarthritides and endomyocarditis. The glands were slightly enlarged in the cervical and axillary regions; liver and spleen were normal. In view of the somewhat peculiar reaction of the patient's blood-forming organs to infection, noted in the history, we record in Table II the data from blood analyses made during her stay in the clinic.

TABLE II

Date of Analysis	Hb %	Erythrocytes	Leucocytes	Rod-nuclears	Polynuclears	Eosinophils	Lymphocytes	Monocytes
Sept. 29, 1936 ..	71	4,230,000	8,400	1	39	7	25	8
Oct. 10, 1936 ..	58	3,780,000	5,300	3	28	2	64	2
Oct. 14, 1936 ..	—	—	10,000	2	43	—	53	2
Oct. 22, 1936 ..	60	3,760,000	6,700	—	41	3	51	2
Nov. 3, 1936 ..	69	4,120,000	6,100	2	56	3	33	6

The recurrence of lymphocytosis (Oct. 10, 14, and 22) is noteworthy in a case of acute polyarthritides, where one ordinarily expects a slightly increased number of neutrophils together with fewer lymphocytes and eosinophils. The subject's lymphatic system produced a different blood picture from that usually described in rheumatic infection. In this case the blood analyses in Table III, made after the patient's recovery and release from the hospital, show the recurrence of lymphocytosis.

TABLE III

Date of Analysis	Hb %	Erythrocytes	Leucocytes	Rod-nuclears	Polynuclears	Eosinophils	Lymphocytes	Monocytes
Nov. 13, 1936 ..	60	3,800,000	10,000	3	55	2	30	10
Nov. 25, 1936 ..	68	4,500,000	6,800	2	41	2	46	6
April 16, 1937 ..	67	4,200,000	6,000	2	45	2	47	4

The patient's lymphatic system reacted with considerable lymphocytosis to both tonsillitis and rheumatism. The occurrence of identical reactions to both these infections is all the more remarkable, because, while in some cases tonsillitis is accompanied by lymphocytosis (although not so marked, it is true, as in our patient), polyarthritides as was revealed here is usually accompanied by relative lymphocytopenia. The data given acquire special interest in view of the fact that, suspecting a connexion between "lymphatic reaction" and leukaemia in the family, as occurred in the first case discussed here, we investigated and found that this patient actually does come from a family affected with leukaemia. Her maternal grandfather, 70 years old, fell ill with leukaemia on June 3, 1935. His blood analysis, done on June 21, showed: Haemoglobin, 51%; erythrocytes, 3,990,000; leucocytes, 177,000 (polynuclears, 75%; lymphocytes, 90.5%; monocytes, 2%).

Clinical examination at this time disclosed considerable enlargement of all lymphatic glands, especially the submaxillary and right axillary. The liver was palpable at the costal margin and the spleen was enlarged. Keeping in mind the instability of the lymphatic system in the grand-daughter, we had the

grandfather taken to hospital on Oct. 19, 1936, and placed under our observation. His condition, with the enlarged lymphatic glands and spleen in conjunction with the blood picture, left no doubt about the nature of his disease—a type case of chronic lymphatic leukaemia. Further investigation disclosed that his elder brother had died in 1909 at the age of 48 of a similar disease.

As our assumption that some connexion exists between leukaemia and specific blood reactions in the members of same family was thus confirmed to a certain extent, naturally sought the reasons for such a connexion in the data available on the other twin, who had died four years previous of tuberculous meningitis.

Twin M had the same diseases in childhood as her sister. On March 5, 1931, M became ill with exudative pleuritis; on April 22 she entered the clinic at the Medico-Genet Institute with a diagnosis of "exudative pleurisy (tuberculo-broncho-adenitis)." A blood analysis made then showed a slight leucocytosis but marked relative lymphocytosis: Haemoglobin, 60%; erythrocytes, 4,450,000; young granulocytes, 0.5%; rod-nuclears, 4.5%; polynuclears, 36.5%; eosinophils, 0.5%; lymphocytes, 64.5%; monocytes, 2.5%; Türk cells, 1%. Although lymphocytosis does occur in pleuritis of tuberculous type, the proportion of lymphocytes (64.5% revealed by the analysis is certainly somewhat unusual.

The patient was kept under observation at a tuberculous dispensary for a month and a half after her discharge from clinic. She died of "tuberculous meningitis" late in July, 1931 at Botkin Hospital. At the necropsy tuberculous infiltration of the left subclavicular region and tuberculous leptomeningitis of the base of the brain were found. During this last illness a blood analysis was made, which, however, disclosed lymphocytosis.

Thus in the family investigated the first twin revealed a peculiar anomaly of the lymphatic system which showed in reaction to infection. There was considerable leucocytosis, the latter rising to 90% and higher. Although we cannot be equally positive in our statements about the second twin, there was undoubtedly a certain peculiarity in the lymphatic reaction to infection. In view of the great rarity of leukaemia itself and the equal or even still greater rarity of reactions such as those here described, the occurrence of both phenomena in members of one and the same family can hardly be regarded as a coincidence. Of particular significance is the second case, where previously made assumptions of leukaemia in the family and lymphocytosis in the second twin were confirmed on investigation. If, as in this case, we note a certain relationship between lymphatic leukaemia and lymphatic reactions in the relatives, the question now arises of the nature of these lymphatic reactions. Are they early or concealed forms? What is their pathogenesis, prognosis, etc.? The material presented in this paper is of course insufficient to warrant an answer to these questions. However, our study case does offer a few indications toward the solution.

*Case 3.*—This case is one of the familial cases described in our first communication. Patient R became ill with chronic lymphatic leukaemia, according to her statement, in October 1932. A blood analysis made in 1927 showed: Haemoglobin, 60%; erythrocytes, 3,350,000; slight lymphocytosis (?); eosinophils, 11%. Roundworms were found in the faeces. A blood analysis taken in 1928 gave the following data: Haemoglobin, 60%; erythrocytes, 5,140,000; leucocytes, 9,000 (eosinophils, 2%; lymphocytes, 55.5%). At that time the patient paid no attention to the lymphocytosis. Towards the end of 1932 she accidentally noticed a swelling of the lymphatic glands in the left axillary region and, later on, in other regions. A blood analysis then showed: Haemoglobin, 65%; erythrocytes, 3,580,000; leucocytes, 150,000 (lymphocytes, 96%).

This marked lymphocytosis dispelled all doubts about the presence of lymphatic leukaemia. Thus we see again a member of a leukaemic family who at one time showed a lymphatic reaction. This case is interesting not so much on account of the lymphatic reaction itself but because we now find the patient presenting a clear picture of chronic lymphatic leukaemia. So far this case is the only one we know of its kind, and no

conclusions can yet be drawn from it. Nevertheless, it does indicate certain possibilities for further investigation into the pathogenesis of leukaemia.

### Discussion

The first two cases present pictures of an atypical course of infection characterized by marked lymphatic reaction. Observations on leukaemoid and lymphatic reactions in infection are not new, and in fact have even served as arguments in favour of the infectious origin of leukaemia. However, what is new in our cases is the fact that all the patients come from families affected with leukaemia. While in the first case we accidentally discovered a leukaemic patient in the subject's family, and in the third case investigated the subject only in the stage of definitely developed lymphatic leukaemia, knowing beforehand that we were dealing with a familial case of leukaemia, the second case differs in that we based upon the existence of a lymphatic reaction in one of the twins the assumption that leukaemia existed in the family and then on investigation found this to be correct. Furthermore, our discovery of leukaemia in this last case led us to assume the presence of a lymphatic reaction in the second twin. To a certain extent this assumption was also confirmed.

It seems to us that chance does not explain the occurrence of a lymphatic reaction in all these cases. In our first communication we had already stated that in lymphatic leukaemia heredity apparently played some role. If we assume the possibility of a poor manifestation of the leukaemia genotype, most probably it would take precisely the form of lymphatic reaction. Naturally it does not follow from this that all individuals exhibiting a lymphatic reaction in some disease must belong to families affected with leukaemia, and on the other hand not all bearers of the leukaemia genes exhibit such a reaction. However, there can be no question but that cases where such a relationship is established cannot be ignored, for they contribute to the explanation of such reactions.

Special consideration must be given to the phenomenon met with in our second case, where the abnormal blood picture remained for a long time. The question may be put as follows: Are we really dealing here with a stable deviation in the blood composition occurring after streptococcal tonsillitis, or is this somewhat variable lymphocytosis simply the peculiar constant state of our subject's lymphatic system? This question can be answered correctly only by comparing the data from blood analyses made before and after the onset of the disease. We give below the data from two of twin A's blood analyses taken from the records of the Medico-Genetical Institute. The first of the two was made in March, 1931, when twin A entered the institute's clinic for the treatment of tuberculous intoxication and broncho-adenitis. The twins were at the time aged 8 years 10 months. Blood analysis: Haemoglobin, 64%; erythrocytes, 3,500,000; leucocytes, 8,200 (rod-nuclears, 1%; polynuclears, 17%; eosinophils, 3.5%; lymphocytes, 72%; monocytes, 4%). The second analysis, dated Dec. 7, 1932, gave the following data: Haemoglobin, 53%; erythrocytes, 4,160,000; leucocytes, 7,300 (rod-nuclears, 2%; polynuclears, 28%; eosinophils, 1%; lymphocytes, 59%; monocytes, 10%). The considerable lymphocytosis revealed in both analyses is unusual for tuberculous intoxication but can be fully explained in this case, as in her tonsillitis, by the instability of the subject's lymphatic system, which reacts with a lymphocytosis to any infection regardless of its origin. At the same time there is another possibility that should not be overlooked—namely, that the lymphocytosis is due to a combination

of two processes: (1) a peculiar condition or "set-up" of the lymphatic system in which a 40–60% leucocyte count is to be considered "normal," and (2) the influence of infection.

The material discussed above, pointing to the possibility that the leukaemia genotype may manifest itself in a peculiar manner—in the cases here described, in lymphatic reaction—takes on special significance in view of the data acquired in recent years by medical genetics in the field of early and latent forms of hereditary diseases. Most pathological genes in man are characterized by poor, sometimes surprisingly low, penetrance. Without going into the theoretical aspect of the problem of penetrance, we believe it useful to emphasize here certain points bearing on the facts discussed in this paper. In a number of researches into such diseases as hypertension (Ryvkin and others), ulcer and cancer of the stomach (Levin and Kuchur), pernicious anaemia (Presnyakov), diabetes insipidus (Pesikova), and other diseases where both the patients and their relatives were clinically examined, the existence of such latent manifestation was confirmed. The patient's relatives showed one or another symptom characteristic for the patient's disease. For example, one may mention the finding of achylia among the relatives of patients with cancer, some disturbance of blood flow and blood pressure among relatives of subjects of hypertension, the achlorhydria in relatives of people with pernicious anaemia, etc. Our material on the expression of the leukaemia gene in man does not present an isolated phenomenon in the hereditary pathology of man.

Mention should be made in this connexion of J. Bauer's opinion that lymphocytic, monocytic, and myeloid reactions are abortive forms of leukaemia. We consider this to be a very interesting but scarcely proved hypothesis. Our investigation throws some light on the nature of these reactions. In future the essential task in studying each individual case of lymphatic reaction will be to complement the usual clinical examination with a thorough family history and investigation of the patient's close relatives.

### Summary

This investigation is devoted to a study of concealed forms of leukaemia. The surprisingly rare manifestation of the leukaemia genotype, combined with the discovery of a peculiar lymphatic reaction in the brother of a leukaemic patient (Case 1), led us to search among the members of families affected with leukaemia for such relatives who might exhibit some symptoms of the disease.

We describe three cases of a peculiar lability on the part of the lymphatic system in several relatives of leukaemic patients. The peculiarity is expressed in a lymphatic reaction, associated in particular with infection.

Besides finding subjects with this lymphatic reaction among the relatives of leukaemic patients (Cases 1 and 3), we worked in the opposite direction and found people with a high leucocyte count in families from which leukaemic patients came (Case 2). Noting a peculiar lymphatic reaction in one twin, we assumed the presence of leukaemic patients in the family; this supposition was confirmed on investigation. A supposition that the second twin must have shown a lymphatic reaction while suffering from some infectious disease was to a certain extent also confirmed.

It would seem that the association between leukaemia and lymphatic reactions is not accidental and must be due to the influence of the leukaemia genotype.

Some indication of the prognosis in cases with these lymphatic reactions can be gained from the third case, where a leukaemic patient had shown a lymphatic reaction four years before falling ill.

This investigation is only a first step in the study of the expression of the leukaemia gene.

## PRODUCTION OF Rh AGGLUTININS ANTI-C AND ANTI-E BY ARTIFICIAL IMMUNIZATION OF VOLUNTEER DONORS

BY

J. J. VAN LOGHEM, M.D.

With the Technical Assistance of Miss M. v. d. HART

(From the Centraal Laboratorium van den  
Bloedtransfusiedienst, Binnengasthuis, Amsterdam)

The Rh agglutinins anti-C and anti-E used for Rh subgroup typing have until now been obtained from mothers and patients with agglutinins induced by Rh antagonism. It is possible to increase the titre of these antibodies by artificial immunization with the specific antigens C or E (R' or R'' cells). If these sera are obtained from Rh-negative persons they usually contain incomplete anti-D antibodies as well.

In order to obtain pure anti-C and anti-E agglutinins without incomplete anti-D the following experiments were performed in the Central Laboratory of the Blood Transfusion Service in Amsterdam.

Rh-negative male volunteer donors were injected with R'r (Cde/cde) and with R''r (cdE/cde) cells. This procedure is very simple.

F. K., a male volunteer donor aged 18, blood group O rr, was treated in the following way.

He received five injections of 2 ml. of R'r cells of group O, followed by seven injections of 0.25 ml. (injections twice a

\* Visible macroscopically. † Weakly positive macroscopically.

week). After a period of rest for nearly six weeks five further injections of 0.25 ml. of blood were given with approximately the same time intervals. During this period no Rh agglutinin were present in his serum. After the last injection of 0.25 of R'r blood (17th injection from the beginning) a chill with rise of temperature resulted. Rh agglutinins type anti-E with titre 1:16 could now be demonstrated (the titre in saline is the same as in albumin). After a new series of nine injections during 27 weeks the titre increased to 1:32 in saline and 1:128 in albumin (see Table I).

In this way it is proved that it is possible to produce pure anti-E antibody by repeated injections with R' cells. Besides the complete anti-E (early-immune) antibody it seems that incomplete (hyperimmune) antibodies type anti-E were also formed.

Encouraged by this success five other male volunteer donors were injected with R' cells, group O (donor Sch. R'R' and donor Dam. R'r). Practically the same procedure of immunization as in the first case was followed. Only one of these donors seemed to be sensitive enough to produce Rh antibodies.

G. de J., a male volunteer donor aged 33, blood group A (see Table II). After the 13th injection Rh agglutinins were

			1:4		1:32	1:8	

\* Visible macroscopically.

present in his serum (titre 1:2). After the 17th injection with R' cells of group O the titre increased to 1:8 (visible macroscopically), 1:16 weakly positive, type anti-C, with incomplete antibodies type anti-D, titre 1:8 (albumin test) without incomplete (or hyperimmune) anti-C. After a new series of 11 injections the titre of anti-C in saline fell to 1:4, but increased in albumin to 1:16. After four more injections the titre in saline was unchanged, but in albumin it increased to 1:32.

Thus it appears to be necessary to stop the immunization at the right moment in order to prevent the production of the hyperimmune antibodies, which sometimes cause a decrease in titre of the early-immune antibodies.

In cases of erythroblastosis foetalis Diamond demonstrated that after repeated immunizations Rh agglutinins (early-immune antibodies) are replaced by (or changed into) Rh-hyperimmune antibodies. In these two cases of artificial immunization these findings could be confirmed

Four other donors treated in the same way have failed to produce Rh agglutinins.

So long as there are found anti-D antibodies of the incomplete type only artificial immunization of male volunteer donors is a useful method in preparing anti-C and anti-E agglutinins.

**Note on the blood of the two donors to G. de J.; by R. R. Race, M.R.C.S., L.R.C.P. (Medical Research Council, Blood Group Research Unit, Lister Institute, London)**

The finding of some anti-D as well as the hoped-for anti-C in the serum of volunteer G. de J. was of considerable theoretical interest, for it appeared that the antigen C might be capable of stimulating the antibody anti-D. It therefore became important to test the cells of the two R' donors as fully as possible in order to detect the antigen D<sup>a</sup> if it should be present. Agglutination tests gave the following results:

	Anti-						
	C	C'	c	D	E	e	
Donor Dam. . .	+	-	+	-	-	+	i.e., apparently Cde/cde (R'r) Cde/Cde (R'R')
Donor Sch. . .	+	-	-	-	-	+	

When these two bloods were further tested with many anti-D sera (using the saline, albumin, and antiglobulin techniques) some of the reactions were positive; that is to say, the samples should more properly be called CD<sup>a</sup>e/cde and CD<sup>a</sup>e/Cde. There are several grades of the D<sup>a</sup> antigen distinguishable by the different proportion of anti-D sera with which they react. The D<sup>a</sup> antigen in these two bloods was low on the scale.

In view of the close relationship between the antigen D and the antigen D<sup>a</sup>, it seems reasonable to attribute the anti-D antibody in the serum of the volunteer to the D<sup>a</sup> antigen present in the blood of both his donors.

## Medical Memoranda

### Two Cases of Fugue after Mepacrine Administration

Although it is by no means certain that the administration of mepacrine ("atebrin") was the cause of the fugues here described it is felt that these case notes should be placed on record because of the striking sequel in both cases to moderately heavy doses of the drug and because of the tragic circumstances which ensued in Case 1. Both cases occurred in the Anglo-Egyptian Sudan.

#### CASE REPORTS

**Case 1.**—The patient, a happily married British woman aged 32, with two children, had no family or personal history of mental disorder and no private worries. She was first seen on Oct. 16, 1945, by a Sudanese doctor in an out-station. She was suffering from fever (temperature 103° F.=39.4° C.) and severe headache. M.T. malaria was diagnosed by blood examination, and the following course of mepacrine was given: First day, 0.3 g. followed by 0.3 g. three hours later; second to fourth days (inclusive), 0.2 g. night and morning—total, 1.8 g. The condition responded quickly to treatment, and on Oct. 19 the patient felt fit and well. She asked permission to play tennis, but this was refused. That night, after dinner, she and her husband retired to bed at about 9.30 o'clock. They chatted for a while in bed and the patient appeared to be her normal cheerful self. The following morning the husband awoke to find that his wife had disappeared. Shortly afterwards some natives arrived with the news that her body had been found in the river. Post-mortem examination showed that death had been due to drowning, and there were no other abnormal findings.

**Case 2.**—A British man aged 47, with no family history of mental disorder, had suffered from claustrophobia after the 1914-18 war due to having been buried alive three times by shell bursts, but the condition had completely cleared up by 1924. I saw him on Nov. 3, 1945, when he was suffering from fever (temperature 101° F.=38.3° C.) and pains in the back and bones. M.T. malaria was diagnosed by blood examination and he was put on the following course of treatment: First day, 0.2 g. of mepacrine followed by 0.2 g. after four hours; second to fifth days (inclusive), 0.1 g. of mepacrine t.d.s.; sixth to tenth days (inclusive), 10 gr. (0.65 g.) of quinine bichlorohydrochloride t.d.s. On the evening of the sixth day of treatment the patient felt sick after taking quinine. On the seventh day, without medical advice, he decided to revert to mepacrine treatment and proceeded to take 0.1 g. t.d.s. On the evening of the ninth day—i.e., after he had taken a total of 2.4 g. of mepacrine he went to his bath at his usual hour of 6 p.m. While sitting in the bath he felt a "feeling of unreality coming over him." The next thing he knew was that he was sitting in his dining-room naked and wet. The interval of amnesia had lasted for about half an hour. Mepacrine was at once stopped and no further ill effects occurred.

I have to acknowledge with thanks the permission of the Director Sudan Medical Service, to publish these notes.

D. R. MACDONALD, M.B., Ch.B., M.R.C.P.,  
Sudan Medical Service.

### Unusual Case of Calcification of the Myocardium

Calcification of the heart to a great extent, without a previous history of pericarditis or other heart disease, is rare, and the facts revealed by the following case report are, I believe unusual.

#### CASE HISTORY

The patient was admitted to hospital when 35 years of age suffering from dementia and mental deficiency. It was stated by his relatives that he had not had any previous illnesses. His clinical record during the whole of his fifteen years in hospital showed that at all times he suffered from slight dyspnoea and cyanosis of both hands and feet, and occasionally he had swelling of the lower extremities. Attendants who were in close contact with the patient during the whole of his hospital life state that although he never actually worked he was quite capable of walking about and attending to his own needs. During the last four years he was confined to his bed, but got up every day for toilet purposes. One morning, fifteen years after admission, just after he had returned to bed he suddenly collapsed and died. He was then 49 years of age.

At necropsy the main pathological changes were found in his heart. This organ was enlarged (weight 360 g.) and felt extremely hard, in fact the usual post-mortem scissors would not cut into its substance, and bone forceps had to be used. The pericardium was fused completely over the whole surface of the left ventricle. The latter on being opened was found to contain ante-mortem clot (see illustration). In the lower two-thirds of the left ventricle there was no muscle tissue left at all; it was simply an ossified wall, which was obviously the result of a fusing of the pericardium and endocardium. This wall had a maximal thickness of 7 mm. The only area where muscular tissue was left was in the upper part of the left ventricle and a very small amount of its apex. The muscular wall of the right ventricle was somewhat hypertrophied and showed no signs of calcification. There was no gross pathological alteration in the valves, nor did the aorta or other arteries exhibit any atheroma or other changes.

## Reviews

### WOMANHOOD

*The Psychology of Women. A Psychoanalytic Interpretation. Volume 2. Motherhood. By Helene Deutsch, M.D. (Pp. 439. 25s.) London: Research Books Ltd. 1947.*

This volume is the second part of the author's psychological study of her own sex. She considers the adult woman and her reactions to all those events that lie in the province of the modern obstetrician and gynaecologist. Her study forms a branch of "psychosomatic" medicine, and though she presents it from the psycho-analytic viewpoint she does not mar it with the dogmatic assertions that sometimes emanate from that school. She acknowledges that many of the deviations from normal in the woman's sexual and maternal life are not readily explicable on purely physical grounds, and suggests that deep-seated mainly unconscious motives, acting through the autonomic nervous system and the endocrine glands, may be responsible for many of these anomalies. When well established they may be no more remediable by psychotherapy than by any other treatment. However, if the processes are understood, disorders may in some cases be prevented, and for that reason obstetricians will find the book worth reading.

The book begins with a study of the social position of women, with special reference to that of American women, whose importance and rarity in pioneering times led to their being highly valued. This natural esteem changed to a romantic and idealistic attitude towards them, which is only slowly fading. Women owe their complexity of character, and the many psychosomatic conditions to which they are subject, to the deep-seated conflicts between their erotic and maternal functions, neither of which can be entirely repressed, and between narcissistic tendencies to aggrandize themselves and altruistic impulses to sacrifice themselves for the sake of mate and child, especially child. Their masculine components likewise conflict with their feminine and may determine the course of their lives or influence it inconsistently. The oral component of their libido is directed externally in giving food and internally in the desire to make the child part of themselves. The author draws attention to the analogy in the unconscious mind between the sexual and digestive functions when discussing the reception of the sperm and the expulsion of the foetus and how these two components of the sexual are separated by the whole period of pregnancy. She gives many examples of the influence of these conflicts on sexual intercourse, conception, pregnancy, parturition, lactation, the mother-child relationship, and the climacteric. She suggests that many cases of sterility, abortion, premature and delayed birth, difficulties in nursing, psychotic hostilities to husband and child in the puerperium and later, and the impulsive and inconsistent behaviour of the change of life are psychically determined. Similar conflicts determine the difficulties in the relationships of unmarried and adoptive mothers, foster-mothers, and stepmothers, and she draws attention particularly to the effects of emotional immaturity, emphasizing the similarities of reaction to these conflicts during puberty and the climacteric. Finally, she discusses the reactions of grandmothers sympathetically. This book deserves the attention of all medical men, whether general practitioners, psychiatrists, or gynaecologists. Although long, it is easy to read, and the interest is sustained.

R. G. GORDON.

### ANTIBIOTIC THERAPY

*Penicillin Therapy, including Streptomycin, Tyrothricin and other Antibiotic Therapy. By John A. Kolmer, M.S., M.D., F.A.C.P. Second edition. (Pp. 339; illustrated. \$6.00.) New York and London: D. Appleton-Century Company. 1947.*

The appearance of a second edition of a work on this subject is a reminder that penicillin has been with us for some time, and Prof. Kolmer is to be congratulated on his powers of digesting what is now a vast literature. He gives as many as 1,437 items in the list of references, and though the reader

might have preferred them in alphabetical order he will be grateful for so comprehensive a guide to original sources. Prof. Kolmer has rearranged the book, now classifying disease regionally instead of aetiological. In the earlier chapters, in which he considers general principles and methods, he still emphasizes the need for thinking in terms of bacterial species and not merely of the position and nature of the lesion. There is the usual list of species classified in three orders of susceptibility, and containing several disputable items—for example, *Proteus* and *Salmonella typhi* might well be promoted both from the third ("slightly susceptible or insusceptible") to the second category ("moderately susceptible"), and *Actinomyces bovis* (hominis), *Erysipelothrix rhusiopathiae*, and *Streptococcus viridans* from the second to the first ("highly susceptible").

Has not the time come when the susceptibility of bacterial species to penicillin should be stated quantitatively instead of in these vague terms? Susceptibility to streptomycin is so stated in this book, although it is far more variable both intrinsically and according to the technique used for determining it. Reverting to the subject of *Salm. typhi*, we find that the author considers penicillin therapy to be ineffective or contraindicated in typhoid fever, and he appears to have overlooked the work of McSweeney and others on the treatment of this disease with penicillin and sulphathiazole given together in large doses. He commends penicillin esters in a passage that was evidently written before it was shown that human blood, unlike the mouse's, contains none of the esterase necessary for liberating penicillin from them. Practitioners in Britain who are exhorted by advertisements or compelled by circumstances to give large intramuscular doses only twice a day will find that Prof. Kolmer does not approve of this practice: the longest interval between doses considered advisable is four hours, except when oil suspensions are used.

This book is for the moment the most up to date and one of the most comprehensive guides to the use of antibiotics (the author also considers streptomycin, tyrothricin, and 14 others). It is a useful work of reference on obscure points and provides sound information on ordinary matters.

L. P. GARROD.

### MIDWIFERY IN GENERAL PRACTICE

*Postgraduate Obstetrics. By William F. Mengert, M.D. Drawings by Ruth Maxwell Sanders. (Pp. 398; 123 illustrations. 25s.) London: Hamish Hamilton Medical Books. 1947.*

This book is written primarily for the general practitioner who does a certain amount of midwifery—attending, the author reckons, about 1,800 maternity cases during his lifetime. Prof. Mengert sets out to consider only those conditions whose frequency is not less than 1 in 2,000 deliveries. Nevertheless, he cannot resist mentioning a few others which, although interesting, are so rare as to be outside the experience of most practitioners. He omits nearly all theory and maintains a practical outlook throughout; there is little room for discussion, and his advice is of necessity dogmatically presented, sometimes in the form of a synopsis. Much of it is excellent, though it does not always conform to views generally accepted in Britain. Some of the methods of treatment described—e.g., the use of intrauterine bags in the treatment of placenta praevia—will be regarded as outmoded, and the technical details of caesarean section, vaginal hysterectomy, post-partum sterilization, biological tests for pregnancy, endometrial biopsy, tubal patency tests, and caudal anaesthesia are hardly of immediate interest to anyone engaged solely in domiciliary midwifery as practised nowadays.

A book of this kind has great possibilities; it requires a careful choice of subjects and a suitable placing of emphasis, and it is doubtful whether any two authorities would agree on them. Prof. Mengert has perhaps attempted too much in a small compass, with the result that his account of many subjects is superficial and unsatisfying. If he had restricted his field more severely and devoted more space and attention to the details of those things that really matter, we could recommend the book more strongly. As it is, some sections are very good and contain many useful practical tips. The author's common sense pervades the book, and his style makes it easy and entertaining reading.

T. N. A. JEFFCOATE.

## PHYSIOTHERAPY

*Massage and Remedial Exercises in Medical and Surgical Conditions.* By Noël Tidy. Seventh edition. (Pp. 480; illustrated. 25s.) Bristol: John Wright and Son 1947.

This book, which has reached a seventh edition in fifteen years, obviously satisfies a need, and we can commend it as a clear and trustworthy guide to the treatment of almost any disease by physiotherapeutic methods. Indeed, it is almost a short systematic account of medicine and surgery, including some pathology and not a little physiology and anatomy. We must criticize such statements as "anterior poliomyelitis is due to a bacillus as yet not definitely identified," or "the bacteria are carried by the lymphatics," and, a few lines later, "the virus first attacks the blood vessels of the anterior horns" (our italics). Such discrepancies are vestiges of the past and should be eliminated from future editions.

We wonder, after reading this book, whether physiotherapeutic procedures are not being used in unsuitable cases. For instance, we see an account of the application of these methods to the treatment of blood diseases—e.g., pernicious anaemia—and haemorrhoids, and the question comes to mind whether the interests of a large profession have not caused disease to become the handmaiden of massage rather than made massage serve the cure of disease. It seems that this branch of treatment, of such great benefit in appropriate cases, is showing signs of becoming a complete system of treatment, like osteopathy, naturopathy, and others. The wide scope of this book is likely to mislead the student into believing that there is scarcely any disease which should not be treated by the methods advocated. It would be unfortunate if this idea spread, for physiotherapy should be used only in certain cases and remain subservient to other forms of treatment.

This criticism of the general trend, however, does not apply to the book under review, which in itself is excellent. The extent to which such methods of treatment should be used is beyond the control of the author of a textbook of this kind, who has to meet a demand. Not a little of the blame for these tendencies lies with our own profession.

N. C. LAKE.

## MANUAL FOR DIABETICS

*Leitfaden für Zuckerkrankhe.* By Dr. Georg R. Constam. (Pp. 127; illustrated. 12.50 Swiss francs.) Basle: Benno Schwabe and Co. 1947.

Close similarity combines with many subtle differences in the numerous books written by diabetic specialists for their patients: this is the most human ever written in the German language, optimistic and friendly. The author discusses all the usual details of diet, insulin injections, tests, and adjustments of treatment in a fairly simple fashion—clear enough, perhaps, to the universally intelligent Swiss but rather too detailed for our "hospital patient."

The food tables are probably the best available for the intelligent patient using a weighing machine. The author has designed them in the English tradition (Lawrence's schemes) and neglected the American Joslin methods, although he acknowledges the merits of both. The basis of his scheme is 10 g. of carbohydrate; in the tables he records the various weights of different foods containing this quantity, and ingeniously lists in another column the percentages of carbohydrate, protein, and fat contained in that weight of food. However, the figures often differ considerably from the values accepted in Britain for common carbohydrate foods (McCance and Widdowson), and he quotes no authority in support of this divergence. Though admirable for the highly intelligent patient, this book has too wide a scope and too much detail. The account of the treatment as well as the prevention of coma and gangrene is too full for the patient's understanding, yet not complete enough to help the medical man.

There are good illustrations of insulin bottles, syringes, the technique of injection, foot exercises, etc., and the production of the book is excellent. In this book there seem to be the seeds of two better ones—a shorter and simpler book for the patient, a longer and more detailed one for the medical practitioner treating diabetics.

R. D. LAWRENCE.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*The Electron Microscope.* By V. E. Cosslett, Ph.D., M.Sc., M.A., F.Inst.P. (Pp. 128. 7s. 6d.) London: Sigma Books. 1947.

A popular account, including illustrations, of electron photomicrographs.

*The Alchemist in Life, Literature and Art.* By J. Read, Ph.D., M.A., Sc.D., F.R.S. (Pp. 100. 10s. 6d.) London: Thomas Nelson and Sons. 1947.

A general account of alchemy by the Professor of Chemistry at St. Andrew's University.

*Traité de Dietétique du Nourrisson.* By M. Lust. (Pp. 539. 1,000 francs.) Paris: Masson et Cie. 1947.

A textbook of infant feeding.

*Riflessi Sociali della Tonsillectomia.* By Guido Calderoli. (Pp. 75. No price.) Bergamo: Carrara. 1947.

Certain aspects of the results of tonsillectomy.

*Illustrations of Regional Anatomy.* 7 Sections. By E. B. Jamieson, M.D. 7th ed. (£3 15s. for 7 sections; singly 12s. 6d.) Edinburgh: E. and S. Livingstone. 1947.

Coloured anatomical diagrams of the human body arranged in loose-leaf folders.

*Cancer of the Breast.* By D. C. L. Fitzwilliams, C.M.G., M.D., Ch.M., F.R.C.S., F.R.C.S.Ed. (Pp. 199. 25s.) London: William Heinemann. 1947.

A general account based on the author's experience.

*Dermatology for Nurses.* By G. H. Percival, M.D., Ph.D., F.R.C.S.Ed., D.P.H., and Elizabeth Toddie, S.R.N. (Pp. 116. 15s.) Edinburgh: E. and S. Livingstone, Ltd. 1947.

The nursing of patients with common skin diseases; illustrations, many in colour.

*Good Health with Diabetes.* By Ian Murray, M.D., F.R.F.P.S.G., F.R.C.P.Ed., and M. B. Muir, S.R.N. (Pp. 40. 2s.) Edinburgh: E. and S. Livingstone. 1947.

A manual of instructions for the diabetic patient.

*Nelson Loose-Leaf Surgery of the Nose and Throat.* Renewal pages. London: Thomas Nelson and Sons. 1947.

*Biological Antioxidants.* Transactions of the First Conference, Oct. 10-11, 1946, New York. Edited by G. C. Mackenzie. (Pp. 81. \$2.) New York: Josiah Macy, Jr., Foundation.

Includes a number of papers on vitamin E in chemistry and biology.

*Conference on Metabolic Aspects of Convalescence.* Transactions of the 13th Meeting, June 10-11, 1946. Edited by E. C. Reifstein, Jr., M.D. (Pp. 232. \$2.) New York: Josiah Macy, Jr., Foundation.

Includes papers on male sex hormones, the adrenal cortex, and parenteral administration of fats.

*Conference on Metabolic Aspects of Convalescence.* Transactions of the 14th Meeting, Nov. 12-13, 1946. Edited by E. C. Reifstein, Jr., M.D. (Pp. 190. \$2.25.) New York: Josiah Macy, Jr., Foundation.

Includes papers on bone metabolism.

*Traitément Chirurgical de la Tuberculose Pulmonaire.* By Henry Joly. (Pp. 282. 820 francs.) Paris: Vigot Frères. 1947.

A general account of surgical measures for pulmonary tuberculosis.

*Pictorial Handbook of Fracture Treatment.* By E. L. Compere, M.D., F.A.C.S., S. W. Banks, M.D., F.A.C.S., and C. L. Compere, M.D., F.A.C.S. 2nd ed. (Pp. 390. \$5.50 or £1 10s. 6d.) Chicago: The Year Book Publishers. London: H. K. Lewis. 1947.

A profusely illustrated manual on the treatment of fractures

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 13 1947

## THE DISCUSSION WITH THE MINISTER

As has already been announced the Minister of Health met the Negotiating Committee on Dec. 2 and 3. During the course of one afternoon and one morning the Minister went over the points made in a long document presented by the Committee, and the outcome of these discussions will soon be laid before the profession in the form of a statement which is expected from the Minister of Health at any moment now. The British Medical Association is sending to every doctor in the country, whether a member of the B.M.A. or not, a copy of the Negotiating Committee's statement together with a copy of the Minister's reply. For the purpose of record these statements will also be published in the *Journal* as well as the statement made by high legal authorities on the interpretation of Sections 35 and 36 of the Act. The Council of the B.M.A. is holding a meeting on Dec. 17 to discuss the present situation and to decide on future action.

## THE TREATMENT OF PNEUMONIA

Twenty years ago no one would have ventured to predict that by the present time three separate forms of specific treatment for pneumonia would have been introduced, each of remarkable efficacy. The first of these, which held the field until towards the end of the last decade, was serum. Refined by Felton's method, latterly prepared in rabbits instead of horses, and ultimately made available for all the thirty then known types of pneumococcus, serum was shown to be capable of reducing the mortality of pneumonia by something like one-half. It may be noted in this connexion that during the war Erna Mörch,<sup>1</sup> working in Copenhagen, extended the list of known types of pneumococcus to over seventy, and the State Serum Institute catered for the serum treatment of infections by every one of these. But serum treatment calls for laboratory and other facilities which are available only in large centres, and its general application would have presented formidable difficulties. The second phase began with the introduction of sulphapyridine in 1938: this drug did all that serum had, and more, with the utmost facility, and rendered serum treatment almost obsolete within a year. The later sulphonamides have achieved equal or better results with much less liability to toxic effects, and if the last word had already been said at that stage there would have been little reason to complain. Yet a third remedy was still to appear, even more remarkable than the first two. Penicillin has two advantages over sulphonamides in the treatment of pneumonia, one of special and one of general application: it attacks pneumococci which are sulphonamide-resistant, and it is entirely free from any danger of serious toxic effects. On the other hand, when used in the conventional way it is much more troublesome to administer.

The present issue of the *Journal* contains four papers bearing on this subject. Two deal with the latest development of penicillin treatment, which is to obviate the difficulty and discomfort of injections by giving the drug by the mouth. Anderson and Landsman (p. 950), of Glasgow, the former with Ferguson<sup>2</sup> having previously found that there is little to choose between sulphonamides and intramuscular penicillin in the treatment of adult pneumonia, have compared intramuscular and oral penicillin in a further series of 90 cases, there being 45 in each group. A substantial proportion of the patients, actually greater in the oral group, had a bacteraemia, which is the clearest possible indication that the series was of at least average severity. The doses used were moderate, the mean total amount used for each patient being only 800,000 units by the intramuscular and 1,650,000 by the oral route. This is by no means extravagant, and the oral dose used is less than that advocated by American authors. Perhaps administration in tablet form in milk and the restriction of fluid intake helped to render this smaller dose effective. As the authors remark, the relative achlorhydria of acute febrile states may also make for better absorption. At all events the results appear to have been excellent: there were only seven deaths in the whole series, all in cases complicated by other grave disease or moribund on admission, and in the duration of fever and the frequency of complications there is little to choose between the two groups. Suchett-Kaye and Latter (p. 953) treated twenty-five cases of pneumonia in infants by giving penicillin in the same form orally at 3-hour intervals, the individual dose varying from 10,000 to 40,000 units according to age. They record observations on the serum-penicillin levels attained, which though variable—as almost everyone has found in studying the effects of oral administration—were usually satisfactory. The results were good, except in four cases which were then treated successfully with sulphamezathine. Infants have a particular claim to oral penicillin, since they need comparatively little of the drug and should be spared the pain and disturbance of injections if possible. As the authors say, the possibility of using penicillin in this way is particularly valuable in circumstances in which injection treatment is actually impracticable.

Joules and Weller, of the Central Middlesex County Hospital (p. 947), have relied on sulphamerazine, at least for the primary treatment of the average case. It is not possible to assess the severity of their cases, and, in view of the dictum in an opening paragraph that in the absence of an influenza epidemic respiratory infections producing fever above 100° F. (37.8° C.) for more than one day have some degree of lung consolidation, it seems possible that they have detected radiologically a number of mild cases which might weight this series in favour of the treatment used. The only deaths, which appear to have been inevitable, occurred in patients treated with sulphamezathine or penicillin. The sulphamerazine-treated patients numbered 113, of whom 3 were also given penicillin from the start, while 27 others were given it later for various indications, such as failure to respond to the initial treatment, intolerance

<sup>1</sup> *Serological Studies on the Pneumococci*. Copenhagen. 1943.  
*Lancet*, 1945, 2, 805.

of the drug, and the discovery that the infection was staphylococcal. Sulphamerazine has the advantage that adequate blood levels can be maintained by eight-hourly administration; the treatment is therefore simplicity itself, and involves the least possible disturbance to the patient. The possibilities of sulphonamide treatment are illustrated from an altogether different angle in the paper by Dr. David-Lehr (p. 943), of New York, which was communicated to the International Physiological Congress in Oxford last July. This paper describes an extensive pharmacological study of the behaviour of mixtures of sulphonamides, from which it is clear that such mixtures overcome one of the principal dangers in the use of these individual drugs; further experience may show that the method has other advantages. The essential fact reported is that ingredients in such mixtures retain their individual solubilities in urine. It is thus possible by administering two or three drugs instead of one, each in a proportionally smaller dose, to reduce very greatly the danger of undue precipitation in the urinary tract. Careful studies on large numbers of animals also showed that these mixtures have a much lower toxicity than an equal dose of a single compound. It also appears that the blood levels attained are higher, owing to the better absorption of a smaller dose of each compound. Finally, clinical results have confirmed therapeutic efficacy and the rarity of crystallization in the urine, and it has been observed that allergic reactions are less common and nausea and vomiting are rare. From every point of view studied this combination of two or three drugs instead of one appears to offer decided advantages.

Which of these methods should now be used for treating a patient with pneumonia? It is right that every promising method should be tried, and reassuring to know that penicillin even when given by the simple oral route is a satisfactory remedy. Nevertheless it would, we think, be unfortunate if this became a routine treatment. It is more expensive, and might prove in more extensive trials to be less regularly reliable than the Glasgow findings suggest, owing to irregularity of absorption, a feature emphasized by all workers who have estimated blood levels and urinary excretion after administration by this route. Moreover, penicillin is a drug to which pneumococci can acquire some degree of resistance, which is then permanent. Would it not be a better policy to retain penicillin as a second line of defence, rather than to bring it into general use when an older and well-tried remedy will still serve so admirably, especially in its most modern forms? As Joules and Weller point out, many cases of pneumonia can satisfactorily be treated at home: the normal course of an average case responding to sulphonamide treatment is that of a two-day fever. If no such response follows, and if the case has unfavourable features from the outset, then hospital treatment is called for and other forms of chemotherapy may be necessary. Ideally the ultimate guide to specific treatment should be a careful examination of the sputum, including mouse inoculation if necessary, and determinations of the sensitivity of the pneumococcus or other organism found to whatever chemotherapeutic agents it is proposed to use. The finding of a sulphonamide-resistant pneumococcus would then call unequivocally for

penicillin treatment, just as the finding of *H. influenzae* or *Bact. Friedländer* would contraindicate it. Penicillin has yet to find its true level. Its novelty and the romance associated with it create a popular demand which the profession should resist when necessary. A vogue for taking it by the mouth might prove an extravagance which we can ill afford.

## AGENE AND CANINE HYSTERIA

The discovery by Sir Edward Mellanby<sup>1</sup> that flour bleached with "agene" produced hysteria in dogs has attracted widespread attention since its publication in the *Journal* at the end of last year. Veterinarians and others concerned with the health of dogs have been most directly interested, but the more important issue is the possibility that agenzized flour may have some injurious effect on man. Since agene, a preparation of nitrogen trichloride, is regularly used in this country to improve the baking properties of flour, problems affecting both the public health and extensive interests in the milling industry may sooner or later have to be faced.

We published recently a further article by Mellanby<sup>2</sup> describing his attempts to find out why agene causes flour to become toxic and to identify the toxic factor. Agenized flour was washed free from starch with water, and the resulting gluten was found to produce hysteria in dogs. Gluten prepared from untreated flour did not cause hysteria. At first sight this would seem to prove that some product made from the protein fraction of the flour is the toxic agent. It is well known, however, that gluten so prepared contains most of the fat originally present in the flour, and that the fat of agenzized flour contains chlorine derived from the nitrogen trichloride. The gluten of agenzized flour was therefore extracted with a mixture of alcohol and ether. When given to dogs the defatted gluten still caused hysteria, while the fatty extract was harmless. An attempt was then made to identify the fraction of the protein made toxic by agene. For this purpose agenzized gluten was extracted with 65% alcohol, and so divided into a soluble "gliadin" fraction and an insoluble "glutelin" fraction. Both fractions caused hysteria, but gliadin appeared to be more toxic than glutelin.

Mellanby's observations have now been confirmed and extended by Dr. T. Moran,<sup>3</sup> director of the Research Association of British Flour Millers. From a consideration of the chemical behaviour of nitrogen trichloride, and from a study of its quantitative effects in changing the acidity of dough, he has concluded that though some of the chlorine liberated by this compound is used for oxidation a substantial proportion combines chemically with the constituents of the flour, either by addition or by substitution. Microbiological tests show that the process of agenzizing flour does not affect any of the better-known members of the vitamin B complex, and, in particular, that there is no loss of pyridoxin (vitamin B<sub>6</sub>). Lack of this vitamin had previously been suggested as a possible cause of hysteria<sup>4</sup> in dogs in view of the observation by Chick, El-Sadr, and

<sup>1</sup> *British Medical Journal*, 1946, 2, 885.

<sup>2</sup> *Ibid.*, 1947, 2, 288.

<sup>3</sup> *Lancet*, 1947, 2, 289.

<sup>4</sup> *British Medical Journal*, 1946, 2, 903.

<sup>5</sup> *Biochem. J.*, 1940, 34, 595.

Worden<sup>5</sup> that its deficiency causes epileptiform fits in rats. Even stronger evidence that a toxic agent rather than dietary deficiency causes canine hysteria was obtained by giving dogs very heavily agenzized flour: 80 mg. of agene was added to each 100 g. of flour, as compared with the 6.4 mg. usually added in routine milling. After a single meal containing flour so treated, dogs developed hysteria within twenty-four hours, obviously much too soon for the development of a deficiency syndrome. Cures were readily effected in a few days by giving untreated flour. Hysteria was provoked in five days by flour treated with 20 mg. of agene per 100 g., and in about the same time by flour which had been treated with 80 mg. of agene and then diluted with three times its weight of untreated flour. The toxic factor was found not to be extracted by water or by fat solvents, which is in agreement with Mellanby's work. Moreover it was again located in the gluten fraction, and on fractionation with 70% alcohol both the soluble and insoluble fractions were found to be injurious.

In his next experiments Moran attacked the problem from a new standpoint and demonstrated clearly that the development of toxicity after treatment with agene is not peculiar to proteins derived from wheat. When dogs were given agenzized casein they had hysteria within twenty-four to forty-eight hours. Similar results were obtained with agenzized zein, the protein of maize, while with agenzized gelatin slight hysteria occurred after ten days. The result with zein is interesting, because this protein is devoid of the amino-acids glycine, tryptophan, and lysine. If toxicity is caused by the action of agene on a specific intramolecular grouping in protein it is clear that these three amino-acids cannot be involved. Another significant point on which Mellanby and Moran agree is that even heavy treatment with free chlorine does not produce in flour whatever changes are responsible for canine hysteria.

In his earlier paper Mellanby<sup>1</sup> contended that agene makes flour injurious by the production of a toxic agent rather than by the destruction of some essential nutrient. These recent developments have fully confirmed this conclusion, though it remains to be decided whether agenzized flour is the only, or even the most important, cause of canine hysteria. The identification of the toxic agent in the near future should not unduly tax the skill of the organic chemist and should help us to answer the crucial question whether or not agenzized flour is harmful to man. In the meantime any feeling of security based on the previous conclusion that animals other than the dog are not susceptible to agene poisoning may be somewhat shaken by Mellanby's recent experience with ferrets. This animal, he has found, develops unmistakable symptoms of hysteria when fed upon agenzized but not when fed on untreated flour.

### ADDISON'S DISEASE IN PREGNANCY

Addison's disease associated with pregnancy is an interesting but rare combination. In 1922 Fitzpatrick<sup>1</sup> summarized eleven cases from the literature and described a personal case. In 1945 van Zwanenberg<sup>2</sup> reported two cases and referred to another fourteen collected from the literature. He concluded, as did Fitzpatrick, that the prognosis is

bad. Of the 13 cases for which details were known 7 ended fatally for the mother, and in 6 the baby was born dead. All the maternal deaths occurred during the puerperium, at which time most cases showed a tendency to an Addisonian crisis. Abortion or the induction of labour did not appear to help, but the two patients who received adrenal cortical extract immediately after labour did not suffer a puerperal crisis. Many of the cases referred to by Zwanenberg date back many years and probably did not receive what would now be regarded as adequate treatment for adrenal cortical failure. Indeed it seems likely that in this disease, as with so many others, the complication of pregnancy becomes increasingly less serious as more efficient methods of treatment are discovered, and in general, it is best to treat the disease and not to interfere with the pregnancy. This suggestion is borne out by recently published reports of three further cases. Murphy tells of a woman treated for Addison's disease by subcutaneous implants of desoxycorticosterone acetate with such good effect that she was well enough to marry and become pregnant. There was no evidence that pregnancy itself had a beneficial effect on the disease, nor was there any reason to believe that it had an adverse influence so that the maintenance dose of desoxycorticosterone had to be increased. Labour was induced because it had not begun three weeks after the calculated date; it then progressed easily and rapidly. The baby was stillborn as a result of multiple looping of the cord round the neck and axillae. In the case described by Samuels, Evans, and McKilvery<sup>3</sup> the condition was also brought under control by implants of desoxycorticosterone before conception took place. Desoxycorticosterone, 6 mg. daily, was given during most of the pregnancy, but the authors consider this was probably unnecessary. There was some evidence that pregnancy had a beneficial effect on the patient, but after delivery Addisonian symptoms recurred and necessitated careful treatment. Estimation of the 17-ketosteroid excretion showed a rise about the sixth month which was maintained until delivery, when the level dropped to what it had been before the pregnancy. It is suggested that this increase in output and the improved condition of the patient were due possibly to the action of the foetal adrenals. A compensatory action on the part of foetal ductless glands has often been postulated in the case of other endocrine disorders such as diabetes mellitus. So far as Addison's disease is concerned the evidence is as yet far from conclusive, and in only one of the patients referred to by Zwanenberg was the condition said to be improved by pregnancy. The occurrence of Addisonian crises soon after delivery is perhaps in favour of the idea, although the stress of labour might be an important factor. The normal adrenal cortex undergoes hypertrophy during pregnancy, so an alternative explanation of occasional observations suggesting that pregnancy has a beneficial effect on Addison's disease could be based on the supposition that remaining small areas of healthy gland undergo hypertrophy. If this were true, however, it might be expected that the good effects of pregnancy would persist for a longer time after delivery and that crises would not occur so early in the puerperium, particularly as in some animals adrenal hypertrophy is even more noticeable in the puerperium than in pregnancy.<sup>4, 6</sup>

S. L. Simpson,<sup>7</sup> who mentions two patients with Addison's disease who survived pregnancy, describes in detail a third case in which the patient had two pregnancies, each resulting in a live child. He emphasizes a feature noted by

<sup>7</sup> *Proc. roy. Soc. Med.*, 1946, 39, 511.

other writers—namely, that pregnancy may precipitate the onset of symptoms of Addison's disease, due presumably to the increased demands made on the adrenals. Moreover, in his case the patient failed to lactate on both occasions. This observation tallies with the results of animal experiments in which it has been shown that bilateral adrenalectomy inhibits lactation unless it is followed by the administration of adequate amounts of adrenal cortical extract. In Simpson's case the regular administration of desoxycorticosterone and sodium chloride during the second pregnancy and puerperium did not bring about lactation, so it would appear that some other cortical factor is necessary. It is noteworthy that in none of the reported cases, irrespective of their treatment, was the uterine action in labour disturbed.

### HORMONE TREATMENT OF CANCER OF THE BREAST

Since the original reports<sup>1,2</sup> in this country on the occasional clinical retrogression of carcinoma of the female breast after the administration of stilboestrol little has been added to our knowledge of the carcinostatic effect of the sex hormones. A recent paper from New York<sup>3</sup> reports the administration of ethinyl oestradiol, a synthetic oestrogen, to 17 patients suffering from mammary cancer. This account shows how inadequate are our yardsticks for estimating the retrogression of human tumours. There is no available method of measuring with reasonable accuracy the volume of even an accessible tumour, and clinical estimates of increase or decrease in size are notoriously fallacious. Only complete disappearance can be accepted as clear proof of a decrease in size.

Certain dramatic qualitative phenomena, however, are acceptable as evidence of retrogression, and these were sometimes seen in the series described by Herrmann and his co-workers. A decrease in size of pre-existent carcinomatous ulcers was observed in two cases and graphically recorded, and there was complete healing of an ulcer in a third case. A decrease in the size of pulmonary metastases was measured radiographically in two cases. A protuberance photographed in profile had flattened out after two months' treatment. In no case did the primary tumour or a metastasis completely disappear. Serial biopsies showed no alteration in the histological or cytological pattern of tumours that appeared to regress under treatment. The microscopical picture altered after treatment in only one tumour, and that increased in size during treatment. In one patient the breast tumour increased in size and fungated rapidly at the very time when a pulmonary metastasis from it appeared to be shrinking.

The authors consider that there was a favourable response in 7 of the 17 cases, and this response was obtained for the most part in women over 60 years of age. In young women oestrogen therapy actually appeared to hasten the growth of the tumour. Of the 17 patients 7 died of the disease, and one of coronary occlusion, within eighteen months of starting treatment. Of the 7 patients who died 5 were under 60 years of age; indeed no patient under 60 years of age survived for longer than eighteen months. This series is a small one, but patients selected for oestrogen therapy are necessarily those who are unsuitable for operation or for radiotherapy or whose disease is resistant to these other forms of treatment. In this sense it is gratifying that their numbers are relatively few and that substantial series are therefore slow to accumulate.

### DRUG ADDICTION

In a comprehensive review<sup>1</sup> of the many therapeutic difficulties presented by the drug addict we are early reminded that addiction is a manifestation of a morbid state and that the victim must be treated as a patient. It is a mistake to apply the term "drug addiction" to all cases in which drugs cause euphoria. The cocaine habit is often just an indulgence in vice rather than a state of true addiction; the taking of cannabis always falls into the former category. For a proper understanding of the state of addiction it is well to refer to Himmelsbach's definition of what he terms a "physical dependence." This is an acquired abnormal state wherein the regular administration of adequate amounts of a drug has, through previous prolonged use, become indispensable for physiological equilibrium. The demonstration of this state can be made only by withdrawal and the production of withdrawal symptoms. They are classified as (a) mild: yawning, lacrimation, sneezing, sweating; (b) moderate: tremor, gooseflesh, anorexia, mydriasis; (c) marked: pyrexia, rise of respiratory rate and systolic blood pressure, insomnia, restlessness; (d) severe: vomiting, diarrhoea, loss of weight.

Not every person who takes a habit-forming drug is a drug addict. Only 19% of patients admitted to the Narcotic Hospital in Lexington were found by Himmelsbach to be really dependent on drugs to an extent sufficient to render their cases suitable for study. It is suggested that many alleged addicts have merely a mild drug-habit with only slight physical dependence. This may be due in great part to the adulteration of supplies by "dope pedlars," and to the recurrent difficulty in obtaining opiates. The importance of the foregoing is that accurate appraisalment of the category to which the patient belongs must precede assessment of treatment. Thus a chronic morphine addict habituated to the drug given therapeutically can be much more readily detoxicated if the therapeutic indication has disappeared than can the morphine addict who is predisposed to addiction and whose unstable mind leads him to search for euphoria. The distinction is not always easy to make, because a potential addict may in fact become one owing to the development of a disease requiring morphine.

The need to consider prophylaxis is emphasized by the statement that no person is immune to opiate addiction; if morphine is given to 100 people regularly for a certain time it will produce abstinence symptoms in all of them. In many countries prophylaxis is already carried as far as can reasonably be expected: control of the sale of drugs and the limitation of their use to doctors, dentists, and veterinary surgeons are governed by stringent regulations. It is suggested that more could be done in the direction of educating doctors to use euphoric drugs only when the simple analgesics fail, and then to aim at an initial dose which while sufficient to relieve pain will not be large enough to cause euphoria. Morphine suppositories are said to have the same therapeutic effect as injections, and should be preferred. Against this it might well be argued that a patient will quickly link the suppositories with relief of pain; furtive self-administration would be simplified for the addict, and nursing attendants would be as likely to use them as an injection. The prescription of cocaine, except for direct application by a surgeon, is never justified. There is no risk in refusing cocaine to an addict, because, in contrast to the use of morphine, dangerous abstinence effects never occur, even in the severest cases.

In treating those addicted to opium and its derivatives it is generally agreed that rapid withdrawal is correct. Institutional treatment is essential. The doses of the drug should be so reduced as to avoid serious withdrawal

<sup>1</sup> *Bull. Hlth. Org. L. O. N.*, 1945-6, 12, No. 4.

symptoms. The aim should be to stop the drug in ten days. More prolonged withdrawal is no more bearable to the patient, while it certainly prolongs the discomfort, and this leads only too often to his discharging himself. This raises the question whether a law for compulsory treatment should not be enacted. Personal liberty for an addict whose mind is warped by craving is hardly in the public interest.

The report recognizes the existence of morphinists and opium eaters who appear to be in an "arrested development" stage of addiction. They remain addicted to small and constant doses of the drug, and are efficient and healthy. Stopping the drug makes them ill and incapable of work. Treatment of this group is unnecessary, and possibly dangerous in that it may lead to true and progressive addiction. The greater part of the report is devoted to a detailed consideration of the methods of cure, and pours a salutary cold douche on the many claims for dramatic cures without tears. This work is admirably compiled and worthy of detailed study by those who may be given the responsibility for the cure of a drug addict. It is the last number of the *Bulletin of the Health Organization of the League of Nations*. Its successor will be the *Bulletin of the World Health Organization*.

### THE TREATMENT OF MYASTHENIA GRAVIS

Although thymectomy has produced dramatic improvement in some cases of myasthenia gravis,<sup>1</sup> and the experimental use of diisopropyl fluorophosphonate has opened up a new field, there are still many patients who continue to get relief from "prostigmin." This substance and others which may enhance its effect form the basis of the medical treatment of the disease. It was in 1936 that Dale, Feldberg, and Vogt<sup>2</sup> showed how acetylcholine is released at voluntary nerve endings when a volley is discharged down the motor nerve. Previously Mary Walker<sup>3</sup> had used physostigmine with striking success in a case of myasthenia gravis, because the disease closely resembled curare poisoning, for which physostigmine was known to be an antidote. Since then its derivatives have been employed, the most successful being prostigmin or "neostigmin"<sup>4</sup> and also neostigmin methyl sulphate.<sup>5</sup> Ephedrine<sup>6</sup> may be given as well with advantage in some cases, and guanidine has also been found helpful.<sup>7</sup> Froke, Margoshes, and Harrell<sup>8</sup> tried guanidine in doses of 25 mg. per kilo of body weight in association with prostigmin and found that subjectively, and also on measurement of the myasthenic response with a recording ergograph, there was material improvement in the patient's muscular efficiency.

It is generally recognized that in myasthenia gravis there is a disorder of the acetylcholine mechanism at the myoneural junctions, but its exact nature is still unknown. Froke and his co-workers have analysed the possibilities. The first, that cholinesterase, which breaks down acetylcholine into choline and acetic acid, is present in excessive amounts, was discounted by the work of Cooke and Passmore.<sup>9</sup> The second, that acetylcholine is not liberated, is ruled out by the action of prostigmin, which merely prevents its destruction. The third is that acetylcholine is found in abnormally small amounts. This might be due to lack of precursor substances, lack of potentiators

substances, or excess of inhibitor substances. This possibility is supported by the observations of Torda and Wolff,<sup>1</sup> who found that the serum of myasthenic patients only produced one-third the amount of acetylcholine synthesized by normal serum in the presence of frog's brain *in vitro*. It is also supported by the direct observation of the effect of prostigmin and acetylcholine in varying amounts in myasthenic patients compared with normal subjects. The last possibility is that the myasthenic muscle fibres might be less sensitive to the action of acetylcholine than those of normal subjects, but there is no doubt that the muscle in myasthenia are unusually sensitive to acetylcholine injected directly into an artery. Minot<sup>7</sup> considered that such might be the reason for any potentiating action which guanidine might have on prostigmin, and it is possible that guanidine makes myasthenic muscle fibres contract more efficiently in the presence of prostigmin. If it does, it will enable a smaller effective dose of prostigmin to be given, as suggested by Froke, Margoshes, and Harrell but it must be remembered that its use in the muscular dystrophies, which was based on a similar theory, proved disappointing.

### AT THE BASE OF THE DUODENAL CAP

Duodenal ulcers occur so commonly that physicians may be forgiven if they get into the habit of attributing to ulceration all deformities of the duodenal cap seen on radiological examination. Other conditions which deform the duodenal cap, though they may be uncommon, should nevertheless be considered; their symptoms may be similar, but they often require different treatment; and the prognosis may be very much better. Hypertrophic pyloric stenosis occasionally occurs in an adult, either as a new condition or because it has persisted from infancy. Katz<sup>1</sup> has recently recorded two examples, of which one falls into the latter group. He agrees with other observers that the radiological appearances in this disorder—crescentic indentation of the base of the duodenal cap, narrowing of the pyloric canal, and hyperperistalsis—are not pathognomonic. Laparotomy should always be undertaken in these cases, for a similar picture may be seen in carcinoma of the stomach.

Prolapse of redundant gastric mucosa into the duodenum is another unfamiliar condition, though Scott,<sup>2</sup> in reporting 14 cases observed during 1,346 successive x-ray examinations of the upper gastro-intestinal tract, maintains that it is not rare. The symptoms may be indistinguishable from those of peptic ulceration, but Appleby<sup>3</sup> considers that there is usually intermittent cramping pain aggravated by food and relieved by vomiting. Though the precise diagnosis of a prolapse of the gastric mucosa into the duodenum can only be suspected from the history, both these authors consider that it can be established by radiology. However, there is some difference of opinion about this: whereas Scott considers that the characteristic picture is that of a central "mushroom" or lobulated "cauliflower-like" negative shadow, Appleby shows that the usual appearance is of a "jockey-cap" type of filling defect together with a normal mucosa. Again, while Scott reports successful results from a local resection of the extra mucosa, Appleby advocates gastrectomy. Whichever procedure is best it is certain that the prolapse may occasionally be so great as to constitute an intussusception of the gastric mucosa with symptoms of obstruction. Eckhoff<sup>4</sup> described such a case; it was successfully treated by local resection of the mucosa.

## THE DANGERS OF GOING TO BED

BY

R. A. J. ASHER, M.D., M.R.C.P.

It is always assumed that the first thing in any illness is to put the patient to bed. Hospital accommodation is always numbered in beds. Illness is measured by the length of time in bed. Doctors are assessed by their bedside manner. Bed is not ordered like a pill or a purge, but is assumed as the basis for all treatment. Yet we should think twice before ordering our patients to bed and realize that beneath the comfort of the blanket there lurks a host of formidable dangers. In "Hymns Ancient and Modern," No. 23, Verse 3, we find:

"Teach me to live that I may dread  
The grave as little as my bed."

It is my intention to justify placing beds and graves in the same category and to increase the amount of dread with which beds are usually regarded. I shall describe some of the major hazards of the bed. There is hardly any part of the body which is immune from its dangers.

**Respiratory System.**—The maintenance of one position allows the collection of bronchial secretions, which, stagnating in the bases, encourage the development of hypostatic pneumonia. Further, the absence of exercise and the diminished respiratory excursion consequent on bed rest prevent the re-expansion of collapsed or diseased lung.

**Blood Vessels.**—Thrombosis and thrombo-embolism are some of the most disabling and lethal catastrophes that bed rest can bring to a patient. The absence of leg movements means that the venous blood lacks the helpful squeeze from the muscles which normally speeds its flow, and the flexion of the thighs (particularly when there is Fowler's position or a knee pillow) obstructs it the more. One theory of phlebothrombosis is that it starts with endothelial damage caused by the weight of the leg on the bed compressing emptied calf veins. Thus it may well be said that thrombophlebitis is the internal counterpart of the bed-sore. We may one day regard a thrombosis to be as much a sign of nursing mismanagement as we do the ordinary bed-sore to-day. It is significant that Hunter, Sneedon, and others, performing post-mortem examinations of the veins of the calf in middle-aged and elderly people who had been in bed a considerable time, found thrombosis of the calf veins in 53% of the cases.

**Skin.**—The frequency and dangers of bed-sores are too well known to need much comment. A large bed-sore in a heavy patient, especially an incontinent one, is a nightmare to the nursing staff, and the pressure points on the heels are often a source of great pain and misery to the patient even if the skin is still unbroken.

**Muscles and Joints.**—The contraction of some muscles and the stretching of others are complications of rest which may cause considerable crippling. Foot-drop is of course the commonest, and stiffness and flexion of the knee-joints probably the next. The weakness and wasting of the general skeletal musculature and the restriction of the excursion of the joints are often manifest in the hobbling, painful gait of the convalescent patient.

**Bones.**—When bones are not used the calcium drains from them, and this disuse osteoporosis can be a serious matter, especially in the elderly. Fractures for that reason may take longer to heal, and the absence of weight-bearing is another reason for delayed union. This is shown by George Perkins's recently published cases where the broken ends of bone, when splinted by a metal plate, did not heal until the plate accidentally broke and the resulting increase in weight-bearing led to rapid bony union. The advantages of the Smith-Petersen pin over older methods of managing intracapsular fractures of the femur are largely due to the shorter time in bed.

**Renal Tract.**—The drain of calcium from the bones that I have just mentioned causes an increased liability to urinary calculi, and both kidney and bladder stones are sometimes in part due to bed rest. Far commoner than this is retention of urine. A patient, particularly a male, with a perfectly normal

urinary tract can find difficulty in using a bottle—probably because of the horizontal position of the body coupled with the nervousness and embarrassment felt on attempting this unnatural, uncomfortable, and unfamiliar method of micturition. In older people this difficulty may lead to acute retention with overflow or to simple incontinence. Bed-sores may develop and keep the patient to bed, so initiating a vicious circle of bedridden incontinence. Prolonged incontinence leads to a deterioration of hygienic morale, and a patient may continue to be incontinent from sanitary sloth rather than urological disease. Getting a patient out of bed may turn him from an incontinent person to a clean one.

**Alimentary Tract.**—This too is not immune from the bad effects of rest in bed. After a few days minor dyspepsias and heartburn may be noticed; the appetite is often lost. Constipation occurs almost invariably, and even if not of grave significance is often a grievous worry to the patient. Its causes are, first, the absence of muscular movement; secondly, the change of environment (no one can say why this causes constipation, but it does); and, thirdly and most important, the difficulties of evacuating the bowel in a hospital bed-pan. On a bed-pan the patient is unable to use his abdominal muscles and his nearness to fellow-patients discomforts him. Precariously engaged in balancing himself, he sits there, poised unhappily above his own excrement in great dissatisfaction and distress. The constipation of bed rest is most harmful in the aged, where retained scybala may lead to a diarrhoea which marks the underlying obstruction. Retention with overflow is nearly as common at the back as in front. Quite-often complete intestinal obstruction can develop from retained faeces, and when enemata fail to shift the scybala digital removal has to be practised—a procedure as unpleasant for the evacuator as for the evacuee.

**Nervous System.**—It is well known that, particularly in the ataxic diseases such as disseminated sclerosis or tabes dorsalis, even a short spell in bed may produce a deterioration of mobility which takes weeks to overcome, and any length of time in bed may leave a patient bedridden many years before the natural course of the disease would have made him so.

**Mental Changes.**—Lastly, consider the mental changes, the demoralizing effects of staying in bed. At the start it may produce fussiness, pettiness, and irritability. The patient may acquire an exaggerated idea of the seriousness of his illness and think, "Surely I must be very ill if I am kept in bed?" At a later stage a dismal lethargy overcomes the victim. He loses the desire to get up and even resents any efforts to extract him from his supine stupor. The end result can be a comatose, vegetable existence in which, like a useless but carefully tended plant, the patient lies permanently in tranquil torpidity.

Even the insomnia and nocturnal restlessness so common in hospital patients may be related to the abuse of rest. Too much sleep during the day means too little sleep at night. You may notice that many patients who disturb the ward at night are flat on their backs snoring during the day. They lie in bed with nothing much to do, and we cannot blame them for taking frequent cat naps. I am sure that many hours of half-sleeping and dozing are less beneficial than a few hours of deep sleep, and I believe they encourage a certain confusion of mind.

So much for the commoner hazards of the bed. There are many I have omitted. I have not mentioned the loss of education in children who are long in bed, nor spoken of the dangerous dust that arises during bed-making, but even those evils I have outlined may help to show that rest in bed is anatomically, physiologically, and psychologically unsound. Look at a patient lying long in bed. What a pathetic picture he makes! The blood clotting in his veins, the lime draining from his bones, the scybala stacking up in his colon, the flesh rotting from his seat, the urine leaking from his distended bladder, and the spirit evaporating from his soul.

I have painted a gloomy and unfair picture: it is not as bad as all that. There is much comfort and healing in the bed, and rest is essential in the management of many illnesses. My object has been to disclose the evils of overdose, and I want now to indicate briefly how some of them may be avoided or overcome.

First, bed rest should be prescribed and not assumed—that is to say, a sister should not confine the patient to bed without the doctor's ordering it. Secondly, doctors should revise their attitude to rest where it is unsound. In a chronic ward of which I once had charge I found a lady who had been in bed for 17 years with a diagnosis of nervous debility and whitlow. She had survived this remarkable hibernation with little damage, and though she was very upset when I ordered her up she became a different person when she was fully ambulant. It may well be, too, that our attitude to rest in more acute cases could be modified. Rheumatic-fever cases are often kept flat on their backs for a considerable time, although there is no evidence that this modifies the incidence of heart complications and there is good evidence that the work of the heart is increased by the supine position. Patients with coronary thrombosis traditionally have six weeks in bed, but the evidence that this diminishes the incidence of complications is slender. Indeed, Sir James Mackenzie, who had frequent angina after cardiac infarction in 1908, never spent more than a few days in bed, but continued playing golf till his exercise tolerance at last became too small. He lived an active and useful life for 17 years after his first attack.

John Powers, of Cooperstown, New York, reported on 100 consecutive patients who were allowed to sit in a chair and walk on the first day after major operations. He compared them with an equal number who remained in bed for 10 to 15 days and found fewer complications in the first group. Further, the early ambulant cases were back at work within 4.8 weeks as compared with 8.7 weeks in the control group. All these facts encourage us to review the traditional amounts of bed rest that we order our patients.

The third way of avoiding the dangers of bed lies in altering the equipment and arrangement of a ward. There should be a day-room attached to every ward and lockers for patients to keep their ordinary clothes in. Too often a sister puts all her patients back to bed as a housewife puts all her plates back in the plate-rack—to make a generally tidy appearance. Too often patients stay in bed because, shuffling round in slippers and dressing-gown, they are cold and uncomfortable. They would welcome a warm day-room with chairs and books. Some heart cases ought to be allowed to spend most of the day in arm-chairs and to sleep the night in them if they feel much more comfortable that way. For those that have to be in bed a commode might be allowed as an alternative to a bed-pan in most cases. More liberal attention should be paid to breathing exercises, limb-moving, and occupational therapy to prevent complications and to distract the patient from going to sleep out of sheer boredom.

"Teach us to live that we may dread  
Unnecessary time in bed.  
Get people up and we may save  
Our patients from an early grave."

## THE ANATOMY OF SPEECH HUXLEY LECTURE

The Huxley Memorial Lecture was delivered before the Royal Anthropological Institute on Nov. 25 by Dr. W. L. H. Duckworth, of Jesus College, Cambridge. Dr. Duckworth's subject was "Some Complexities of Human Structure," and he took as his text the remark of Huxley in 1865 that anthropology was the science which unravelled such complexities. He confined his review to the organs of speech and the parts of the brain with which speech is associated.

### Lips and Tongue

Employment in the production of articulate speech was not the only function performed by the lips; they still played a part in gesture, of which use the South African bushman provided a good example. In spoken and gesture language alike the agents used were the facial muscles. Some eight or nine muscles converged on each side of the two angles of the mouth, where they merged in an area specially responsive to traction exercised by muscle fibres. One group of the muscles concerned was the so-called labial tractors, consisting of fibres entering the substance of the lip almost perpendicularly, from

above or below. Some of these fibres penetrated not only the peripheral fibres of the orbicularis oris but the marginal fibres as well; such penetration was said to provide a contrast between human lips and those of the chimpanzee, in which the marginal fibres were barely reached. The variety of movements around the aperture of the mouth was no less important than the variety of parts found in the mechanism. These movements were essentially skilled, and it was permissible to suppose that in future they would become very much more skilled than at present.

Comparison of the tongue in the various types of mankind rested mainly on observations of the sensory papillae distributed over its surface. The papillae combined in lines to reproduce the letters V or Y, but the angle at which the divergent arms of the letter were inclined to one another was subject to considerable variation and to interruption. The tongue, like the lips, could be protruded and withdrawn, and comparative anatomy suggested that these movements appeared early in the evolutionary history of the tongue or its representatives. The connexions both of the intrinsic and extrinsic muscles deserved further exploration. More than half a century ago Macalister declared that there was reason to believe that the musculature of the tongue varied in different races—a statement which did not seem to have been disproved.

### Lower Jaw, Soft Palate, and Larynx

The lower jaw had been very fully studied. In articulated speech the movements of the jaw evidently involved certain muscles whose study was inseparable from that of the bone itself. Some of these muscles made no direct connexion with the tongue, while others entered the substance of the tongue as its extrinsic muscles. The lecturer added that evaluation of the human lower jaw had not been rendered more simple by acquiescence in the view that the Pitted mandible belonged to an individual whose brain, as inferred from the skull, suggested, if it did not prove, endowment with human speech.

The soft palate combined with the hard palate and the tongue in contributing to the production of speech. Its tendency to assert its existence in snoring was almost pathological. Study of comparable sections from the soft palate of an Australian aboriginal and an African negro had not so far provided any suggestion of specific peculiarities.

The larynx appeared to be simply constructed, but its parts were numerous. The intersection and interlacement of the fibres of the thyro-arytenoid muscles were now known to be much more complex than was previously believed. The importance of the muscle was evident in view of its close relation to the vocal fold, for it was thus at the very source of sound production in the larynx.

Reviewing these various vocal organs as a whole, the lecturer said that it was worth while inquiring whether they displayed any similarity in their structural complexity. In the lips, the soft palate, and the vocal folds alike muscular fibres were conspicuous, and with a slight exception all were of the striate variety. In each instance they tended to surround a passage or cavity the width or dimensions of which they varied by their action or relaxation. The tongue was different in some respects, but it would not be impossible to present the tongue as an example of extraordinary specialization of the muscular tissue surrounding the cavity of the mouth, while as to the mandible this was an ossification in a great sheet of muscle stretching from one temporal region to the other. While a general agreement of scheme might thus appear, a marvellous amount of differentiation accompanied it.

### Speech Centres

Turning finally to the parts of the brain associated with speech, Dr. Duckworth spoke particularly of two areas in the left cerebral hemisphere (in right-handed persons), namely, on the frontal lobe, mainly in front of the central sulcus, and on the parietal lobe, comprising the supra-marginal, angular, and posterior parietal convolutions. Disintegration of the first of these areas affected speech strongly, if it did not always abolish it. There was failure to co-ordinate the contribution of the lips, tongue, and soft palate, and vocalization became a continuous cry or grunt, not controlled by the patient. Persons suffering from disease of the left posterior parietal

involution could speak, but were likely to talk nonsense and be unable to comprehend spoken or written language. The first area was concerned with the co-ordination of muscular actions; the second with comprehension of things seen or heard or the impressions of muscular sense. In both areas the human brain exhibited structural features indicating progress in advance of the highest apes, and, in regard to the second area, a much higher development than in other animals. The organs he had reviewed, said the lecturer in conclusion, were common to mankind and to a large number of animals. Detection of distinctive human characteristics was comparatively easy when the countenance or the brain were in question, but their parts called for the knowledge furnished by dissection and the study of microscopical preparations. With this assistance, systems such as the facial muscles, including those of the lips, had yielded evidence of the outstanding position of mankind. Further research should be encouraged. Despite the vast demands of phonetics, linguistics, and psychology, the anatomist should not be deterred from participation in the biological study of the organs of speech. This claim was made in view of a remarkable passage in which Huxley ninety years ago expressed approval of

those who have not made the mistake of attempting to approach biology, either by the high *a priori* road of mere philosophical speculation, or by the mere low *a posteriori* lane offered by the tube of a microscope, but have taken the trouble to become acquainted with well ascertained facts and with their history."

The wise anatomist would treat these words with due respect, but he might recall also Huxley's citation as the last words of his lectures on the morphology of the vertebrate skull in 1864: "*Nil actum reputans si quid supersesset agendum.*"

## THE MEDICAL WITNESS

### PRACTITIONERS AND THE COURTS

A large number of senior students and newly qualified practitioners assembled in the Great Hall of B.M.A. House on Dec. 2 for a lecture arranged by the Metropolitan Counties Branch, on "The Medical Witness." The lecture was given by Dr. Robert Forbes, secretary of the Medical Defence Union, and the chair was taken by Mr. A. M. A. Moore, later supported by Dr. E. A. Gregg, president of the Branch.

Dr. Forbes said that medical practitioners appeared in courts more frequently than other technical witnesses or members of other professions, and it was conceded by those capable of forming a judgment that in the main they conducted themselves with acceptance and with a consciousness of the important duty they were undertaking. Doctors appeared as ordinary or as expert witnesses. As ordinary witnesses the rules of evidence had to be modified in a certain respect to admit of their testimony, for they were expected to give not only, like other witnesses, their version of the facts but also the inferences to be drawn from them. The expert witness was in a different category. He was not compelled to appear for either side. On being asked to consider the matter, he would indicate what the facts submitted to him signified in his opinion and whether or not his evidence was likely to be of value to the plaintiff or defendant as the case might be. Most doctors considered themselves to be "expert" witnesses in any event, and that in one sense was true, though not according to the legal definition and acceptance of the term. They were, in the main, witnesses to facts, unless they happened to have had special experience or knowledge and to have had no preliminary connexion with the case at issue.

The necessity for keeping records of examination and treatment of patients was emphasized. Incidents regarded as insignificant at the time might come to have a great importance if litigation ensued. Such records were necessary for the protection of the practitioner should he be challenged in a civil or criminal case. Hospital records were often also called for in court, but were not really evidence unless the person who made them was available in court to speak to the notes.

#### Obedience to Subpoena

The practitioner appearing in a case would usually be asked first to make a report, which would form the proof of evidence. From that moment he should act with the utmost circumspec-

tion, making sure that no phrase in that report was such as he could not honestly support in oral evidence. Nothing was more unfortunate during a hearing than that a statement upon which counsel had opened his case should be found at a later stage to require modification. Exaggeration and theorizing—the two rocks upon which many practitioners foundered on their first appearance as medical witnesses—must be avoided. Facts must be defined with exactitude, and the case put no higher than could be substantiated under cross-examination. Partisanship, also, should be eschewed. It was common for a doctor to think that, once employed by a side, he must support their point of view; he should remember that he was there to assist the court to arrive at the facts and that he should leave it to the court to decide the issues. He should try to keep an open mind, always remembering that he might not be aware of all the facts, and that some of his inferences might have to be altered as the case proceeded.

If a subpoena were issued upon a practitioner, and conduct money tendered, and the case were a criminal one, the practitioner was obliged to attend. In a civil action, if a subpoena was served and conduct money not tendered, he was not obliged to attend, but he would be ill advised to refuse. He should indicate to the judge before he was sworn that he had not received conduct money or any fee; this matter should be settled at the outset to avoid subsequent recriminations. It was possible and desirable in a civil action to negotiate with the solicitor in the preliminary stage as to the fees to be paid for current and future services, and to get a letter from him indicating his acceptance of personal responsibility for the payment of the specified fees. At the present moment a B.M.A. Committee was proposing that in civil actions the fee paid to the medical witness for giving evidence on fact only should be 10 guineas for a full day and 7 guineas for a half-day, and for an expert witness that the fee for qualifying—that is, for examining or considering the case so as to give the necessary evidence—should be 10 guineas a day, plus 25 guineas a day for giving evidence.

The history of the tender of conduct money and the payment of a sum for board and lodging was interesting. In days gone by it was laid down that only a "gentleman" was entitled to payment under these heads, and thus it became necessary to define a "gentleman." First the legal authorities admitted that a physician or a surgeon fell within the category of a gentleman; a little later they included a solicitor, and later still a surveyor or architect, and they had not gone much further.

Failure to obey a subpoena might mean imprisonment for contempt of court, and in a civil case it might mean action by a litigant if he could show that he had suffered material damage by the witness's absence or that his case might have been won if the witness had been present. A subpoena should be treated with respect. Possibly on arrival at court the practitioner would find a preceding case still in progress, with many witnesses still to be called, but the heaviest case might collapse suddenly, and the practitioner should not go away without getting definite instructions as to when his case was likely to be heard.

#### In the Witness-box

Dr. Forbes gave some practical advice on demeanour in the witness-box. The witness should turn slightly towards the judge, and speak clearly and slowly, bearing in mind that the judge was taking notes. He should not resent the humour of some judges nor be intimidated by the formality and severity of others. He should speak so far as possible in non-technical language; after all, he was there virtually as an interpreter. He should not say that the victim was suffering from "confusion of the integuments under the left orbit, with extravasation of blood and ecchymoses in the surrounding cellular tissues, which were in a tumefied state," when in fact he meant that he had a black eye.

Cross-examining counsel in these days were not in the least of the bullying Buzfuz type; there were snave and friendly, possibly inviting the witness to say that he had been qualified for a long time and had had extensive experience, and generally leading him up the garden path. "Don't let cross-examining counsel make you out to be a bigger dog than you are." A proper humility in the witness would impress the judge. It was important not to lose one's temper under cross-

examination, also not to start to argue with counsel. One must beware of the double question and ask that it be divided. The hypothetical question might be encountered: "Now, doctor, if eighteen months ago when you were first called to see this patient you had the knowledge you now have, don't you think you would have done differently?" It was better to be frank and to refuse to theorize on a hypothetical situation. Another piece of advice was that if the witness got the better of counsel he should be careful not to preen himself upon it by nodding to the judge and adopting a "cocky" attitude.

The procedure of endeavouring to agree the evidence with the other side before the case was heard had a great deal to commend it. Sometimes such conferences resulted in settlement out of court. They helped in any event to diminish the likelihood of that unfortunate occurrence whereby one row of doctors said one thing, followed by another row who said exactly the opposite. That left a bad impression, though, of course, on occasion there might be technical issues that were open to doubt, and there were practitioners who must express opposing views about the same case.

### Privilege

Finally Dr. Forbes dealt with the debated question of privilege. Not uncommonly a doctor was asked to disclose that his patient had suffered, for example, from syphilis or gonorrhoea. This was not a thing he should voluntarily disclose either to the solicitors or to court, unless, of course, the patient was a consenting party. The privilege vested in the patient, and only the patient could release that privilege. It was open to the medical witness to explain to the judge, before or after he took the oath, that he had been subpoenaed and that he might be asked questions the answer to which would be a breach of professional confidence. He might appeal to the judge to decide whether the questions were admissible. But there was no privilege. A doctor must tell if ordered by the court so to do unless he was prepared to accept imprisonment for contempt of court. Solicitors and barristers enjoyed absolute privilege, but not doctors. The doctor must do what he was told by the judge, but he should do it only after he had made his protest and done all in his power to protect the confidence of his patient.

The speaker concluded by urging the members of his audience when newly qualified to join a reputable medical defence organization to secure assistance in these problems when necessary.

## Preparations and Appliances

### OXYGEN UNIT FOR NEWBORN INFANTS

Dr. P. C. D. MACCLANCY, assistant paediatrician, Rotunda Hospital, Dublin, writes: The oxygen unit here illustrated (Fig. 1) has been designed as a simple and portable means of providing efficient oxygen therapy for the newborn infant.

The plastic top, 8 by 12 by 10 in. (20 by 30 by 25 cm.), is made from three lengths of 1/4-in. (6-mm.) "perspex" clear sheet, the centre length being heat-moulded to shape. The sides are joined together by plastic screws and rendered gas-tight by a soluble chloroform weld. The curved opening on the distal side, 7 1/4 in. (17.5 cm.) wide by 5 1/4 in. (12.6 cm.) high, is surrounded by five grooved plastic blocks which hold the "collar" of the apron in place. The apron, 42 in. (1.07 m.) long by 24 in. (0.62 m.) wide, is made from plastic curtain material, which is sandwiched between two curved pieces of 1/4-in. perspex sheet 9 in. (22.5 cm.) wide by 6 1/4 in. (15.1 cm.) high. The curved pieces are joined together by plastic screws and the joints rendered gas-tight as above. A 20-c.ft. (0.56-m.) oxygen cylinder will be found the most convenient size to use, as at the rate necessary to maintain the desired concentration it will last some 8 to 10 hours; further, owing to its relatively small size and weight it is readily portable. The cylinder is fitted with a standard B.O.C. unit comprising pressure-reducing

valve, contents gauge, and dry bobbin flowmeter. The oxygen is passed from this to the plastic top via an ordinary Woulfe's bottle.

To provide a concentration of 45-50% oxygen it is necessary to flood the unit at 2 litres of oxygen for two minutes. This concentration can then be maintained by cutting the flow rate down to 1 litre a minute. The carbon dioxide is absorbed by soda lime, some 6 oz. (170 g.) being sufficient for the life of a 20-c.ft. cylinder. The soda lime is put in a wire-mesh container, which is accommodated in a convenient place distant

FIG. 1.—Components of the unit.

from the infant's head inside the plastic top. If it is desired, the plastic top can be used alone without the apron; however, if this is done it will be necessary to increase the flow rate to not less than 3 litres a minute to maintain 45-50% oxygen concentration. A rubber hot-water bottle will be found the most convenient means of maintaining the infant's body heat. Heating by electricity is not encouraged unless it can be provided from a closed and spark-proof element. In hospital we use it in the special premature cots so fitted, but here the unit

FIG. 2.—The unit in use.

is shown in an ordinary drop-side cot (Fig. 2), a type which is mostly employed in households to-day.

The unit described has given every satisfaction over an extensive trial period in the infants' department of the Rotunda Hospital, and it is intended to have some more constructed, when the plastic top will be "bubble-blown," and consequently devoid of any joinings which may not remain gas-tight in use. It was constructed to my design by Max Models Ltd., Dublin, in conjunction with Medical Gases Ltd., Dublin, who supplied the oxygen fittings.

My thanks are due to Dr. Ninian McI. Falkiner, Master, Rotunda Hospital, and to my senior colleague, Dr. W. R. F. Collis, for permission to publish this description.

## Correspondence

### Thiouracil in Toxic Goitre

SIR.—While congratulating Dr. Harold Cookson and Dr. F. H. Staines on their meticulous and unbiased record (Nov. 15, p. 759) of their four years' experience of the use of thiouracil in toxic goitre, we wonder whether they have really provided evidence for their claim that "there is no doubt that the antithyroid drugs now available have established themselves as a most valuable addition to the methods of treatment of toxic goitre, and in certain types as the method of choice." It would, indeed, appear to us that their experience constitutes the most devastating indictment of the use of these drugs in treatment that we have yet read. We do not for a moment question their findings, for they are in line with those of many other observers both in America and in Great Britain, but we do question their conclusions.

The facts appear to be as follows: (1) 95 patients were treated. (2) In 6 no control was obtained. (3) Remission of the disease lasting from 2 to 25 months was obtained in only 40 patients; 15 of these had relapsed. (4) 14 patients suffered from toxic effects of the drug with its abandonment on this account in 2 cases and with one death from agranulocytosis. (5) *No fewer than 10 patients died while under treatment.* Items (3) and (4) in this list contain sufficiently formidable implications of wasted time and effort on the part of both doctors and patients. But it is a mortality, while under treatment, of over 10% that constitutes the most damning evidence of all.

Although 8 of their patients had to be submitted to surgery without a fatality, the writers of the article do not permit themselves any general comparison between their results and those of surgery. They can scarcely be unaware, however, since it has been stated on many occasions, that subtotal thyroidectomy, given good surgery and good management both pre- and post-operative, can be performed on hundreds of consecutive patients with a mortality of less than 1%. These series include patients of all ages and with every degree of severity of the disease (none are rejected), and it is recognized with gratitude that thiouracil is of the greatest service in the preparation of severely toxic patients for surgery.

Dr. Cookson and Dr. Staines have treated 16 patients who had reached the stage of auricular fibrillation. In only half of these was a normal rhythm restored with thiouracil, and 4 died while under treatment. Surgery, on the other hand, claims many of its most brilliant results from among this very seriously ill group of patients, and with the occasional help of quinidine less than 20% fail to obtain a persistently normal rhythm.

In view of these well-established claims we do not understand how the writers of this article can conclude that thiouracil can be the best method of treatment in any type of the disease. It may be argued that the best surgery is not available for more than a fraction of the sufferers from thyrotoxicosis. If this be so, our answer is that opportunity is available for any surgeon to learn the technique and management of the operation. There is no excuse at this date for the plea of ignorance, and it would be bad surgery indeed that resulted in the loss of over 10% of its patients.—We are, etc.,

GEORGEY KEYNES.  
J. W. LINNELL.

London, W.1.

### Diet and the Nation's Health

SIR.—No cautious man would willingly descend into the dusty arena where the gladiators contend about the state of the nation's nutrition, and I formally disavow any expression of opinion on the subject here. I am moved to commentary, however, by the account in your pages (Nov. 29, p. 882) of a recent debate of the Hunterian Society. Sir Jack Drummond, it would seem, expressed the view that there is "no objective evidence showing with clarity and precision" that we are less well nourished than in 1938, and implied that he is not prepared to accept "merely subjective impressions" in a contrary sense.

His antithesis, suited perhaps to the occasion, is resounding rather than substantial, yet he may be right in the first part of his statement. But surely to assume that in so saying he has

disposed of the problem under discussion is to beg the question and to display a misunderstanding of the nature of the problems facing the clinician, the obligations laid upon him, and the means by which he has to deal with both. "Subjective" impressions, and with all respect to Sir Jack Drummond I confess that I know of no other kind, are surely the beginning, if not the end, of that observational approach from which all scientific inquiry must start—an approach, too, that must remain the clinician's principal one.

Every clinician yearns for nature to provide him with "objective data showing with clarity and precision" what is wrong with his patient, and desires whenever possible to measure, verify, and control his observations and to confirm his preliminary impressions. But he knows that too often this is not the order in which things happen in the practice of medicine, that he is constantly being forced to pay careful attention to his subjective impressions and to lay and initiate plans of action in the interests of his patients long before clarity and precision of data are vouchsafed him. If he is not willing to go to work in this way, then he is incompetent to discharge his obligations and were better employed conducting nutritional experiments on rats in a laboratory. There, at any rate, he could afford to wait for clarity and precision, to let time do his thinking for him, and to see his animals visibly pining before he was under the painful necessity of making up his mind. How wonderful it would be did such easy options govern the labours of the physician, who would then rarely be compelled to call upon intuition or to use judgment but could sit back waiting for complete data to drop into his lap.

I suggest, therefore, that where the health of human beings is in question scornfully to reject subjective impressions as part of the material of judgment, and to decline to celebrate in the absence of data of complete clarity and precision, would be as unscientific and negligent as to suppose that subjective impressions are of themselves wholly adequate as evidence and absolve us from the obligation of all further inquiry. In the present instance, perhaps, it is of little importance what the physician thinks or says, since he has no control over what the nation gets to eat; but that one who has been a scientific adviser to the Ministry of Food should take the narrow view of evidence reflected in Sir Jack Drummond's remarks is more serious. He may be right in thinking that the nation is not undernourished, but his criteria of assessment are inadequate to a situation which he appears not to understand.

The biochemist, indeed, has proved notably insensitive to intimations reaching him from medicine, and our bones might easily rattle under our hides before his convention of scientific purism permitted him to see that we were growing empty. If one were at all cynical, one might be tempted to hope that this nation may never be so very hungry that the biochemist comes to notice the fact.—I am, etc.,

London, W.1.

### Acute Non-specific Gastro-enteritis

SIR.—In view of the increasing attention directed to outbreaks of gastro-enteritis of unknown aetiology, a description of an outbreak in this mental hospital last summer may be of interest. The first case began on June 9, the outbreak proper on July 17, and thereafter fresh cases appeared for 30 days, involving 65 out of 309 patients.

The outbreak began in an infirmary ward, where, contrary to the experience of Cook and Marmion,<sup>1</sup> it involved 41% of the patients, principally the old and feeble and those debilitated by other diseases. Eight days later cases appeared in two other wards, the day after that in a fourth, the whole of the female block now being affected. Cases of gastro-enteritis were present in the district, but in the hospital were limited entirely to the female wards. Two female part-time nurses developed it; one had had no direct contact with the affected wards, the other had been nursing there. Some members of the male staff living at home contracted it, but did not infect any of their patients. As in other outbreaks, food as a source could be excluded, as both male and female patients ate from a common kitchen. There was no association with Sonne dysentery,<sup>2</sup> upper respiratory infections<sup>3</sup> or chilling.<sup>4</sup>

Clinically the onset was abrupt, with diarrhoea, vomiting, and gripping abdominal pain; it was apyrexial except in 3 cases, where the temperature rose 1°-2° F. (0.6°-1.1° C.) to subside in 24 hours.

The vomiting ceased within 24 or at the most 48 hours, while the diarrhoea, which was of frequent, offensive, watery stools without blood or mucus, lasted two to three days, exceptionally four or more. In a few the onset was severe with marked prostration. One-fifth of the cases had no vomiting. Each case had a minimum of 3 stool cultures, 201 specimens in all being examined. No organism of the enteric, dysentery, or salmonella groups was found except in one case. This patient's illness lasted longer than usual—namely, 7 days. On the first, fourth, and eighteenth days from the onset her stool was negative; on the twenty-fourth day *Salmonella typhimurium* was isolated. She was the only patient to have a further attack (not shown in these figures), which occurred two months after

the first, when her stools were again negative. Widal tests from this patient and 6 others on Sept. 17 were negative. The following organisms were also identified, the numbers in brackets referring to cases: Morgan's bacillus 1 (4), Morgan's bacillus 2 (1), paracolon-bacillus type (4), *B. faecalis alkaligenes* (1).

All cases were immediately isolated, discovery frequently depending entirely on the nurses' observation. In all but the infirmary ward strict isolation of individual patients could be enforced. Treatment was on the usual lines, with initial starvation and gradual return to normal of the diet by the fourth or fifth day. Attempts to increase the diet more quickly led to recurrence of the diarrhoea. Some cases were given phthalylsulphathiazole 3 g. daily without marked effect on symptoms or duration. However, sulphaguanidine and phthalylsulphathiazole were tried as prophylactics, as shown in the table and diagram. The results were encouraging.

Ward	Population	Type	No. of Cases	Duration	Prophylaxis	% Affected
1	90	Infirmary; aged and sick; overcrowded	37	July 17–Aug. 5	Phthalylsulphathiazole, 1 g. b.i.d. for 2 days	41
2	88	Refractory overcrowded	15	July 25–Aug. 8	Phthalylsulphathiazole, 1 g. t.d.s. for 3 days	17
3	98	Overcrowded; patients out to work	10	July 24–Aug. 4	Sulphaguanidine, 2 g. t.d.s. for 2 days	10.2
4	33	Parole; not overcrowded	2	July 24–Aug. 16	None	6

When sulphaguanidine was given to all patients in Ward 3 the incidence of fresh cases stopped abruptly; one case appeared on the second day of prophylaxis, but her symptoms were mild and lasted only 24 hours. In Ward 1 phthalylsulphathiazole could be given to only a proportion of patients owing to low stocks. Two cases occurred on the second day of treatment and one the day following, all in patients who had been given the drug. Probably the dosage was too small. Fresh cases continued to occur in Ward 2 until phthalylsulphathiazole in a somewhat higher dosage was given to all patients.

An interesting point is that in Ward 4, where no measures beyond isolation of the patients affected were taken, only two developed gastro-enteritis. Here there was no overcrowding and the patients were out most of the day. In Wards 1 and 2 there was close all-day contact between patients, and in Ward 3 close contact all night and part of the day.

The course of the outbreak suggests that the initial cases were caused by one or more carriers from outside and that infection

thereafter spread directly from case to case, probably air-borne. Social functions were in abeyance, and so there was no contact between male and female patients. The sulphonamides appear to have a definite prophylactic value, but further trial would be necessary before a positive statement could be made. Similar claims were made for mepacrine which have not been borne out.<sup>1</sup> Even allowing their value, the incidence was directly related to the degree of overcrowding. The exceptionally high incidence in the infirmary ward may be explained by the difficulty of completely isolating so many, of "spotting" ear cases among the totally demented by an already overworked nursing staff, and of controlling the excretions of the faecal incontinents.

The clinical course of the illness suggested a rapid invasion with most of the damage at the outset, which may explain why the sulphonamides were effective in prophylaxis but not in treatment.—I am, etc.,

Bracebridge Heath Hospital, nr. Lincoln.

#### "Q" Fever

SIR,—I was more than interested in the article on "Q" fever by Drs. J. E. Caughey and J. A. Dudgeon (Nov. 1, p. 694). We do I remember reading the article in question on "Primary Atypical Pneumonia" which has turned out to be an epidemic of "Q" fever. The lesson to be learned from this is of prime importance in my opinion. To my mind it is a great pity that the term primary atypical pneumonia was ever introduced because at the best it is vague, confusing, apt to be misleading, and falls readily from the lips of those who are satisfied with diagnosis which usually depends on so-called typical radiological appearances in the lungs or, in their absence, on so-called typical findings on auscultation of the chest together with the general symptoms of a febrile virus infection, a white count usually below 10,000 per c.mm., and the occasional presence of a rash, splenomegaly, lymphadenopathy, etc. The presence of cold agglutinins in the serum is said to place the diagnosis beyond all shadow of doubt, but greatest stress is usually laid on the radiological findings and the physical signs in the chest.

Physicians who have much experience of febrile diseases, especially prolonged febrile illness in tropical and subtropical countries, realize how often there are present abnormal signs on auscultation of the chest, but these as well as positive radiological findings in the lungs do not necessarily result in a diagnosis of pneumonia of some sort—e.g., primary atypical pneumonia, "pneumonia," or "pneumonitis." Such cases, with or without evidence of radiological findings in the lungs and with a white-blood count of less than 10,000–12,000 per c.mm., are invariably investigated along the lines of a case of P.U.O., which includes blood films and thick drops for malarial parasites, blood cultures, repeated total and differential white-blood counts, appropriate agglutination reactions when facilities are available, and the other relevant investigations. I wonder how many cases of enteric-group fever, other septicaemias, and typhus-group fever, etc., have been diagnosed as primary atypical pneumonia or just "pneumonia."

I never make a diagnosis of primary atypical pneumonia until the last resort, as I believe that such a diagnosis should not be made until all relevant investigations have been carried out and all other relevant causes have been excluded. In this way errors in diagnosis should be lessened. Too often are certain febrile diseases excluded on the degree of the severity of the signs and symptoms or on the absence of some so-called typical sign or symptom. The converse is also true. This attitude is indicative perhaps of book knowledge and is characteristic of self-confidence in the inexperienced. Not infrequently I have seen physicians on clinical grounds alone exclude, with what appeared to be confidence and to their own satisfaction, such diseases as enteric-group fever, typhus-group fever, leishmaniasis, hepatic amoebiasis, and even plague, while later laboratory evidence revealed the true nature of the diagnosis. Surely it is about time that it was universally appreciated that specialist investigations are not just carried out to confirm a clinical diagnosis. Happily that day is at least passing—although not quickly enough—because so often such specialist investigations are necessary to make the diagnosis. Unfortunately some young physicians go to the opposite extreme

## CASE HISTORY

**T**HE patient was injured in July 1941, when his ship was bombed and machine gunned. Examination showed the lower lip divided and a loss of soft tissue of chin and of mandible from right molar region to left incisors. On the 29th August, 1941, two tube pedicles were raised on the neck. These were lengthened four weeks later. On the 22nd October, the scars were excised from the face and the two pedicles attached. November 11th, 1941.—The pedicles divided.

Fig. 2

# LOSS OF SOFT TISSUE OF CHIN AND OF MANDIBLE

Gypsona as an adjuvant in reparative surgery

February 24th, 1942.—A bone graft was inserted.  
June 26th, 1942.—An acromio thoracic tube pedicle was raised.  
July 22nd, 1942.—The pedicle lengthened.  
July 31st, 1942.—The pedicle attached one end.  
September 24th, 1942.—The pedicle attached the other end.  
February 19th, 1943.—A further bone graft was inserted with Gypsona P.O.P. headcap and plaster between each pair of pins.  
October 20th, 1943.—Chin dimple made.

The details and illustrations are of an actual case. T. J. Smith & Nephew Ltd., of Hull, manufacturers of Elastoplast and Gypsona, publish this instance typical of many in which their products have been used with success.

## the NEW analgesic...

'First reports on the use of 'Physeptone' in general practice indicate that an outstanding advance has been made in the treatment of severe pain. With few exceptions, it may with advantage replace morphine, to which it is equal or superior in analgesic effect. 'Physeptone' does not unduly depress respiration, constipate, or induce narcosis or mental apathy; it may be given continuously for long periods without diminution of effect.

'Physeptone' is available in ampoules of 10 mgm. in 1 c.c., in boxes of 12 at 9/-, plus 2/3 purchase tax. For oral administration it is available as 'Tabloid' brand compressed products, 5 mgm., in bottles of 25 at 4/6, plus 1/1½ purchase tax, and bottles of 100 at 16/10, plus 4/2½ purchase tax.

SUBJECT TO PROFESSIONAL DISCOUNT

## 'MYANESIN'

The new muscle relaxant

**NOW AVAILABLE**

Clinical trials, involving its use in over a thousand cases, have clearly shown the value of 'Myanesin' for the relaxation of abdominal muscle in surgery.

'Myanesin' was discovered in the B.D.H. Research Department. It is an entirely synthetic substance of known and constant chemical composition [ $\alpha$ :  $\beta$ -dihydroxy- $\gamma$ -(2-methylphenoxy)-propane].

'Myanesin' is now available as a 10 per cent. solution in ampoules of 10 ml. issued in boxes of 3 and 12 ampoules.

## When patients need more VITAMIN C

In the many cases where supplementary Vitamin C is called for, Rose Hip Syrup is an excellent choice. It is extremely palatable, simple to administer, and is readily tolerated by patients of all ages.

Scott & Turner's Rose Hip Syrup provides an ample intake of Vitamin C in all scorbutic and sub-scorbutic conditions—loss of weight, proneness to infection, anorexia and disordered blood picture. It is made from freshly-gathered rose hips which are exceptionally rich in ascorbic acid, and is prepared in accordance with the Ministry of Health standard (200 mgs. ascorbic acid per 100 mls.).

With its added sugar syrup, Scott & Turner's Rose Hip Syrup is pleasantly sweet. It may be given undiluted, or diluted with water or milk; or added to porridge, cereals and milk puddings. A dessertspoonful contains approximately 25 mgs. ascorbic acid. From chemists only, 1/9 per 6-oz. bottle.

Sample bottle for clinical trial on request.

## DERIPHYLLIN

THEOPHYLLIN and DI-ETHANOLAMINE

Indicated in

**Cardiac Decompensation, Oedema,  
Angina Pectoris and Cardiac Asthma**

Deriphyllin has a regulating action on water metabolism and influences the cardiac mechanism. By dilating the coronary vessels and relieving any coronary spasm which may be present an improved flow of blood through the heart-muscle is secured.

Deriphyllin is exceedingly well tolerated and may be given for a long time (chronic cardiac decompensation) without reaction occurring. Effect does not decrease after prolonged administration. Can be usefully combined with the organic mercurial diuretics. Not contra-indicated in renal disease.

Deriphyllin-Strophanthin is indicated for all cases of heart failure.

Available in liquid form for oral use,  
ampoules and suppositories.

Literature and samples on request.

**CAMDEN CHEMICAL COMPANY LIMITED**

61, GRAY'S INN ROAD, LONDON, W.C.1

and carry out all sorts of specialist investigations before taking an adequate history or making a thorough clinical examination. No doubt the pendulum will settle. The ability to think of likely and not unlikely causes of an illness and their adequate exclusion is what is wanted and not just the ability to repeat verbatim textbook description of disease—a not uncommon failing.

What is pneumonia and what is primary atypical pneumonia? Surely there are different causes of pneumonia, some of which are known—e.g.: (1) Bacterial pneumonia, which may be due to pneumococci, staphylococci, streptococci, *B. tuberculosis*, *B. typhosus*, and *B. pestis*, etc. These are further differentiated by their sensitivity or otherwise to penicillin and/or sulphathiazole, etc. (2) Virus pneumonia due to known and unknown viruses—e.g., influenza pneumonia, psittacosis, so-called primary atypical pneumonia, etc. (3) Malarial pneumonia, pulmonary amoebiasis, pneumonia due to ascariasis and relapsing fever. (4) Pulmonary manifestations of yeasts and fungi. (5) So-called rheumatic pneumonia. (6) Lipoid pneumonia, and no doubt other causes of pulmonary pathology apt to be diagnosed as pneumonia or pneumonitis.

Each infecting agent may produce a typical or atypical picture, so why label one type of infection believed to be due to a virus as primary atypical pneumonia? Why not call it just a virus pneumonia, or, in the present state of our knowledge, why not just describe it as a case of P.U.O.? In cases so labelled exhaustive investigations are invariably carried out. Accordingly I would suggest that febrile illnesses of indeterminate origin should not be given what appears to be a definite diagnosis as "primary atypical pneumonia" would appear to be, otherwise encouragement would be given to the use of the term in cases of febrile illnesses with abnormal signs in the chest the origin of which is not known, vague, or uncertain. Well do I realize that many physicians to-day regard signs in the chest in a febrile illness of doubtful origin merely as a pulmonary manifestation of a generalized disease process and search assiduously for the cause. For them, as well as for those who leap to a diagnosis of "pneumonia" and to the rapid exhibition of penicillin and/or sulphathiazole, the paper of Caughey and Dudgeon should be invaluable.—I am, etc.,

B.A.O.R.

JOHN MACKAY-DICK.

### BAL and Malnutrition of the Nervous System

SIR.—Dr. W. Russell Brain in his most valuable contribution (Nov. 15, p. 763) referred to Peters's work on BAL. May I state this had also caught my interest. Among those who gave so much help in West Africa one must mention the name of A. Clark. The writer met him on his arrival there and owes much to his guidance. It marked also a friendship which lasted till his death in New Zealand early this year. At that time I had come to the conclusion that the food cause of nutritional reticulobulbar neuritis, with its associated conditions, was due to manioc ("gari").

In the therapeutic field naturally one was wholly dependent on knowledge gained from the biochemist. Neither nicotinic acid nor riboflavin had then been discovered. Clark was a biochemist, and his views greatly impressed me, for he advanced the theory that manioc, like sugar-cane in the West Indies (where H. H. Scott had described an identical syndrome, though of a more fulminating type), contained a cyanic glucoside, and this inhibited sulphur utilization by combining with it to form a thiocyanate and so prevent acute poisoning; but if the intake of protein itself was insufficient, then this condition was precipitated. I must add, however, for a number of reasons affecting one's later inquiries, I do not consider Clark's theory can be directly maintained.

I carried out a number of therapeutic trials with various sulphur derivatives, including intravenous sodium thiosulphate, but I found personally they all failed to influence the condition (see *W. Afr. med. J.*, 1937, 9, 35). But this is not a reason, for it was appreciated one was not really using an assimilable sulphur. Following extensive inquiries in other parts of the world, it had become clear that neither manioc nor sugar-cane could be wholly incriminated, as the syndrome could recur independently of either. Thus the Malayan dietary at Changi (where Landon and Pallister demonstrated this condition in 1935) showed the staple carbohydrate was rice. Again we know now, of course, part of the syndrome at least was due to an arboflavinosis, though how much the neural lesions are due to that is problematical. So far as a food cause could be identified we had not advanced very materially from the old "Deeks theory" of excess carbohydrate-diminished protein intake, though one feels it is reasonable to add it had become possible to show that only certain carbohydrate sources of a specified type appeared more

directly involved—cf. manioc, sugar-cane, and "English" rice. Also there was no doubt of the protective value of certain protein foods.

In the therapeutic field by 1938 (Moore, *J. trop. Med. Hyg.*, 1939, 42, 109) it had also become possible to show autoclaved "marmite" (excluding vitamin B<sub>12</sub>) cured the earlier case of nutritional reticulobulbar neuritis just as formerly it had been shown to respond to ordinary marmite. Nicotinic acid had no appreciable effect. But I have always felt Clark had touched on part of the truth, and it is possible that, under conditions of dietaries already referred to, sulphur metabolism may be disturbed. I am not qualified to express any views as a biochemist, and one's own investigations have always been centred on clinical, therapeutic, and dietary survey of these cases. It seems also to the writer it is more than coincidental that arsenic can bear some comparative clinical relationship with these deficiency syndromes. Therefore it might repay us to test Clark's work further, and this supposition, by the use of BAL, which has been only recently discovered. It might prove of interest also to try BAL on swayback. Clark was extremely familiar with this animal-deficiency disease in New Zealand and referred to it in his arguments. (Here again he maintained the cause was a cyanic glucoside in the white clover, and he viewed cobalt as protective.)

Clark's work is published mainly in the *Trans. roy. Soc. trop. Med. Hyg.*, 1932, 26, 301; *Certain Aspects of Poisoning by Food Plants in Nigeria, 1934-6*; *J. trop. Med. Hyg.*, 1936, 39, 269; and from 1936 onwards in a series of articles in the *J. trop. Med. Hyg.* Admittedly the suggestion for therapeutic trial with BAL is conjectural, but to the writer it does seem worth while to explore in active cases, so far as is possible, every avenue which may present itself, provided we do not risk delay in effective treatment.—I am, etc.,

Cheltenham.

D. FITZGERALD MOORE.

### Battle Neurosis Treated with Leucotomy

SIR.—The article by Drs. William Sargant and C. M. Stewart (Nov. 29, p. 866) raises some interesting and perhaps controversial issues. There is no mention or speculation in the report as to the factors underlying the emotional conflict which manifested itself in neurotic symptoms. This does not, of course, mean that the psychodynamic viewpoint was not considered, but may it not be the absence of any discussion on this basis that tends to cause uneasiness among psychiatrists at reports of the more radical physical treatment of the psychoneuroses? This is not to say that there is no justification of the treatment of any particular case by such methods, as electric convulsion therapy and leucotomy. Indeed, facilities for the treatment of chronic psychoneurosis are nowadays so limited that any method which produces results has to be considered. Nevertheless, as long as psychoneurosis is conceded to be the result of emotional conflict, are we not entitled to know or at least to inquire what are the pertinent factors in such cases?

In the case reported the pre-morbid personality gives indications of obsessional traits and might be designated an obsessional character. That the patient had a high morale is suggested by his leaving a safe civilian job for a highly combative one for which events proved he was ill-suited and which led to increasing tension and finally breakdown. One may speculate as to the subsequent history of this case had the war ended in November, 1944, at which time a slight wound had given him an honourable exit from battle. The real conflict which led to a persistence of his symptoms after that time may well have arisen from the feeling of failure in the high task which he had set himself. Intense guilt feelings may have been aroused from which the personality appears to have struggled wildly to escape by paranoid, hysterical, hypochondriacal, and depressive reactions.

"He always seemed unable to gain insight into his symptoms" might surely have been interpreted that the personality could not tolerate this insight, and in this lay no doubt the lack of success with abreactive and exploratory methods and the amelioration of the condition by sedation. Whether a more gradual and long-term psychotherapeutic approach such as psycho-analysis would have produced a better result is a matter for speculation. This might at least have succeeded in modifying the superego and enabled the personality of the whole to suffer less from feelings of guilt.

Might one not speculate as to whether prefrontal leucotomy does much the same thing as this but at some cost, not properly known at the present time, to the personality as a whole?

These, Sir, are briefly the findings in this case, and I consider it rare and interesting for the following reasons. (1) The heart condition seems to have been a toxic myocarditis causing ectopic ventricular beats. (2) The toxæmia was mild, causing no temperature or tachycardia. (3) In my library I cannot find any cardiograms like the tracings found in this case. (4) The clinically alarming condition of her heart and the rapidity with which it cleared up.—I am, etc.,

Roscommon, Eire.

JOHN J. WALLS.

### Obstetric Emergency Service.

SIR,—Mr. Frank Stabler's excellent paper on the Newcastle-upon-Tyne obstetric emergency service (Nov. 29, p. 878) gives me an opportunity to make a point of which I became convinced as an obstetric H.S. and the value of which I have since had a chance to confirm in general practice. This is, that the general practitioner's obstetric bag should include either saline or plasma and a giving set. If he is to be called by the midwife in emergency he should at least bring these simple requirements; in this way he may very well save some of those cases which the "flying squad" admittedly cannot reach in time. He can put up a drip before undertaking manual removal of the placenta—a precaution which I find gives considerably increased confidence. Should the flying squad be called they arrive to find the transfusion arrangements ready set up and can the more quickly continue with any obstetric manipulations that may be necessary.

I would suggest that the regional transfusion officers might organize the supply and turnover of saline and standard giving sets to practitioners. After all, since the war there must be very few practitioners under the age of 50 unfamiliar with simple transfusion apparatus. The supply of plasma might, however, be impracticable. Such apparatus will also come in useful in pit accidents, and its availability on the spot has saved the life of one of my fellow practitioner's patients in this area.—I am, etc.,

Morpett, Northumberland.

R. P. ROBERTSON.

SIR,—If penicillin resistance is to raise its hydra head, manual removal of placenta may well regain pride of place as the most dangerous operation in midwifery. One pictures the modern scene. By the time Mr. F. Stabler has scrubbed up and donned a pair of dry sterile gloves (another pair, of the right size, lying ready in case he tears the first), sister has "woaded" the patient from navel to knees, a sterile towel is on the abdomen, another occludes the rectum, the vagina has been swabbed with flavine, and another expert has anaesthetized the patient. It is probable that in these circumstances running in and out of the uterus as advised may not end in disaster.

But what of the occasional obstetrician in the back of beyond who knows that Mr. Stabler cannot reach him and the blanched woman under two hours? Hastily scrubbing up, he pours pure "dettol" on his hands and "washes" till tacky, anxiously eyeing the while inexpert chloroform dripping at one end and red blood at the other. Introducing a hand he separates the placenta all round and delivers it—*horribile dictu*—by pulling on the cord, and then feels round for debris. Obviously the uterus cannot invert with the hand in the fundus; the membranes are not more likely to be torn than by fingers scratching about inside; and only one introduction is required. One would of course not dare to say this had one not heard it advocated by a most distinguished London gynaecologist.—I am, etc.,

London, E.4.

FREDERIC SANDERS.

### "Unjustified" Use of d-Tubocurarine Chloride

SIR,—I hesitate, as an obstetrician, to enter into this correspondence between two such experts, but as I understand it the uses of curare in this respect are that (a) it greatly diminishes the tendency to spasm, making intubation, if necessary, easier; (b) it enables the entire anaesthetic to be conducted on an exceptionally light plane so that the infant, not being "anaesthetized," cries almost as soon as the head is born and the patient almost before leaving the theatre is becoming conscious; (c) it "potentiates" the action of the barbiturate, thereby lessening the required dose. These reasons Dr. T. Cecil Gray has already expounded. Dr. A. H. Galley (Nov. 22, p. 840) has

scarcely viewed the matter from the standpoint of the obstetrician when he states that "the only possible reason for administering curare preparations to caesarean sections must be for its effect in relaxing the tone of the abdominal musculature." In point of fact, while a fair degree of relaxation is obviously desirable in the initial stages of the operation, it is clearly not asked for with the same urgency as in general surgical procedures in the upper abdomen.

In so far as uterine tone is said to be enhanced by this type of anaesthesia, the problems in pure physics inherent in the contracting uterus simplex at the onset of labour are sufficiently complex as surely to make it unlikely that one may justifiably cite a simple relationship between "kemithal"—cyclopropane anaesthesia and the "eyeful of liquor" which incommoded the present P.R.C.O.G. The incident was disturbing but did not necessarily prove very much, and with optimum conditions such an incident could, I imagine, be repeated quite easily under local anaesthesia. The essential point which I would make is that as an obstetrician one bears a heavy responsibility, not for one life but for two. The mother is frequently ill prepared for a major surgical procedure in comparison with what her state of preparedness would have been for most procedures in general surgery, and the influence particularly of the older types of inhalation anaesthesia on the foetus is too well known to need emphasis. The technique that my colleague Dr. Gray described so well in the *Journal* of April 5 (p. 444), and with which I have now had a fair experience in collaboration with him and other expert anaesthetists, seems to me to offer the obstetrician a few more significant advantages than a little added relaxation of the abdominal musculature, which in any case can often be done without in the initial phase of the operation.—I am, etc.,

Liverpool.

### Diabetes Insipidus and Hyperostosis Frontalis

SIR,—I have read with great interest Prof. G. Marañón's article about diabetes insipidus and uterine atony (Nov. 15, p. 769), but I am surprised that he does not discuss the possible significance of the slight frontal hyperostosis disclosed by the radiograph. Could that hyperostosis not be the "non-malignant non-progressive lesion of small size" for which he looks? It is known that patients with hyperostosis frontalis interna have frequently cerebral symptoms and signs and particularly those pointing to the hypothalamic-pituitary region.—I am, etc.,

Harrow Weald, Middlesex.

### Oxytocic Action of Ascorbic Acid

SIR,—Prof. Chassat Moir emphasized<sup>1,2</sup> the proper use of pituitary extract and ergometrine during and after labour. Dale's<sup>3</sup> discovery and Hofbauer's<sup>4</sup> practical application of the remarkable physiological action of posterior-pituitary extract on the gravid uterus, and Dudley and Moir's<sup>5</sup> isolation of ergometrine, are corner-stones in the advance of conservative midwifery.

The dangers of employing pituitary extract for induction and acceleration of labour have been stressed repeatedly. Chassat Moir's golden rules for the use of standardized pituitary preparations should be strictly observed by all who practise midwifery. With considerable interest I have therefore collected experience about the use of ascorbic acid as an oxytocic agent in labour, having had in mind the disadvantages of pituitary-extract preparations in the first and second stage of labour. My observations, which are based on several hundred deliveries, confirm the views of Kappeli,<sup>6</sup> of the gynaecological university clinic in Berne, that ascorbic acid has a distinct influence on uterine contractility.

I found that the time of employment is chiefly the dilatation period. Contractions must be established. It has, therefore, no effect on an inactive uterus. For induction of labour I found it unsuccessful. Ascorbic acid is used in the first stage, cervix 2-3 fingers wide, when uterine contractions are less than one in three minutes and weak. It is administered preferably by mouth, 100 mg. of ascorbic acid for three doses at half-hourly intervals. If there is no effect the drug can be given in three 6-hourly courses within 24 hours. A 1-min. (0.06-ml.) dose of

"pitocin" can be given after the third dose of ascorbic acid if desirable, often with a very notable oxytocic effect. Higher doses of ascorbic acid are useless. Intravenous use may lead to tonic contractions. Intramuscular administration is of no advantage.

Ascorbic acid proved especially useful in patients with uterine inertia, in which posterior-pituitary extracts were contraindicated. There were no ill effects in mother or baby. In malpresentation, trial labour, antepartum haemorrhage, and foetal distress, where the use of other oxytocics needs greatest supervision and caution in dosage, ascorbic acid is safe and deserves a trial before any other oxytocic agent. Toxaemias of pregnancy are a great field for the use of ascorbic acid as an oxytocic.

It is worth noting that, with the above qualifications, ascorbic acid seems to me an active oxytocic drug which is preferable to posterior-pituitary extract, especially for patients with hypotonia in the dilatation period. The object of this communication is to call for further experimental and practical investigations of a relatively simple and safe chemical substance which appears to regulate and stimulate contractions on the already active gravid uterus.—I am, etc.,

London, W.1.

### Dwarfism, Hormones, and Dieting

SIR.—Dwarfism associated with hypogonadism may be of endocrine origin and may respond to gonadotrophic hormone, testosterone, or anterior-pituitary growth hormone. Preparations of the latter at present available are, on the whole, disappointing, although in October I showed a patient of 15 years of age with infantilism at the Royal Society of Medicine (Endocrine Section) who had grown 3 in. (7.6 cm.) in a few weeks on large doses of growth hormone at a total cost of £60, or £240, the available preparations being of American origin. The local reactions to these large doses—e.g., 5 ml. b.d.—were severe and painful.

In October, 1946, at one of my hospital out-patient clinics I saw a boy of 15, height 4 ft. 6½ in. (138.4 cm.) with hypogonadism, whom I proceeded to treat with thyroid and pituitary growth hormone (by injection) until April, 1947, at the end of which period of six months he had grown 5/8 in. (1.6 cm.). I then lost sight of him for five months, and when he reappeared in September of this year he had grown a further 2½ in. (6.3 cm.) in a period of five months. I assumed at first that he had carried on with the treatment, but I was informed by his mother that he had had no treatment whatsoever but had gone to some relatives on a farm in Ireland and had enjoyed open air and some very good food. In the few months he has been home he has ceased to grow. It is difficult to believe that the growth was unrelated to the period of five months in Ireland.

I am reminded of the work of my old professor, the late Sir Frederick Gowland Hopkins, on the importance of animal proteins and some of the amino-acids essential for growth—e.g., tryptophan and lysine. I am also reminded of the experiments of Corry Mann many years ago (1926), who showed that if the population of a large poor-school were divided into two sections and one half received an extra pint (568 ml.) of milk daily the children in that section grew 1 in. (2.54 cm.) per annum more than those of the control section.—I am, etc.,

London, W.1.

### Remuneration of Specialists

SIR.—A factor which should be considered in regard to the remuneration of a specialist is length of the necessary apprenticeship, though responsibility and annual turnover of patients may also be relevant. It is not reasonable for the man who has worked for a year or two at a special subject and obtained a diploma to expect the same returns as the man who has worked for a higher qualification and is prepared to spend possibly ten years earning little and acquiring the experience to establish himself.—I am, etc.,

London, W.1.

GEOFFREY HALLETT.

### Space for X-ray Departments

SIR.—The carefully thought-out plan for a hospital unit which accompanies the article by Mr. H. J. McCurich on "A Suggested Hospital Unit" (Nov. 22, p. 832) has reminded me once more of the oblivion into which the Recommendations of the British X-Ray and Radium Protection Committee have fallen. This otherwise admirable scheme allows approximately 14 ft. by 11 ft. (4.3 m. by 3.4 m.) for the x-ray room and 5 ft. by 5 ft. (1.5 m. by 1.5 m.) for the dark room and a similar size of store room. The Recommendations referred to above stipulate a minimum floor area of 250 square ft. (23.4 sq. m.) for x-ray rooms and 100 square ft. (9.2 sq. m.) for dark rooms. It is astonishing that only 154 and 25 square ft. (14.2 and 6.7 sq. m.) respectively should have been allowed.

The author expressly states that the plan does not claim to be perfect in detail and mentions the desirability of having the plaster room and x-ray room adjoining. But what interests me is that a plan should be prepared which so flagrantly violates recommendations that are supposed to be accepted by the responsible medical bodies of this country.

Recently another firm of hospital architects raised no objection to a proposal to put an x-ray department in a basement until I drew their attention to the existence of the Recommendations. It was then found that the proposal originated with the architects of the Ministry of Health. On pointing out that one of the Recommendations was that x-ray departments including dark rooms should not be situated below ground level, the proposal was dropped, but my attention was drawn to the fact that many other hospitals have x-ray departments in basements.

Among numerous others the Westminster Hospital, one of the most recently planned and built of large teaching hospitals, has its x-ray department below ground level, I am informed. If this is so, it merely emphasizes the extent to which the Recommendations have been forgotten. They are expressly stated to be minimum requirements and not optimum objectives, and I feel that they should be resurrected and enforced in the way that building by-laws are.—I am, etc.,

Richmond, Surrey.

DOUGLAS GORDON.

### Blepharospasm

SIR.—Among the various tics which we are called upon to treat probably none is more frequent or intractable than the twitching eyelid. Some time ago I was consulted by a patient who was greatly distressed by this condition, which had persisted for nearly a month. He had only decided to get medical advice when on the previous day the ear on the affected side began to ache. When I examined the ear it was full of hard wax, the removal of which was followed by an almost immediate and dramatic cessation of the tic, which has not recurred. Since then I have treated another patient for the same trouble in similar fashion, with almost immediate relief of the condition. In this case, however, there was no accompanying earache, deafness, or tinnitus to guide one.

I am writing this because in such literature as I have by me on the subject the causes of tics are variously listed as errors of refraction, conjunctivitis, carious or unerupted teeth, phimosis, worms, adenoids, and constipation. I find no mention of cerumen auris as an exciting cause, a condition which one may easily fail to consider.—I am, etc.,

West Malvern, Worcs.

W. G. SHAKESPEARE.

### Health Centres

SIR.—I read with great interest Dr. S. F. Logan Dahne's letter (Nov. 8, p. 744) on the subject of health centres. It seems to me that such a development does give promise of an improvement in the medical services of this country, and it fits in admirably with an idea I have had in mind for some time as to the organization of the hospital service.

For this purpose I should like to see the country divided into areas, each with its base hospital staffed by whole-time consultants and specialists. These would preferably not be on a whole-time salaried basis. The base hospital would be surrounded by satellite (local) hospitals, staffed by such of the local G.P.s as had the desire, ability, and experience to take

up a part-time specialty. A close liaison is a simple matter between the G.P. and the part-time specialist, who both live in the same neighbourhood, and there should also be regular visits by the "part-timer" to the base hospital. These visits would enable him to keep in touch with the appropriate consultant and also to follow up cases which he and/or the G.P. had passed on there. I venture to think that the doctor who sends a case into hospital would then learn much more from doing so than he does at present, when all he gets is apt to be a curt note to say that his patient had a swollen head, has been decapitated, and please send him to out-patients in four weeks.

Part-time specialism does not seem to be in favour in high circles, but I believe it is the best, if not the only, way of maintaining and improving the knowledge, skill, and clinical sense of a large part of the profession, and it should be remembered that however skilled the specialist service may be the patient will not derive full benefit from it unless the G.P. is sufficiently knowledgeable to ensure that he reaches the right specialist at the right moment.

Such a scheme would be far more difficult to initiate than the mere "administrative snuffer" which the present Act inflicts upon us all, but taken in conjunction with Dr. Dahne's proposals it appears to me to offer a much greater prospect of improving the knowledge and skill of the individual doctor, without which surely no improvement in the Health Service of the nation is possible.—I am, etc.,

London, N.W.8.

J. H. RANDALE.

### Contact Lenses

SIR,—Mr. A. G. Cross (Nov. 22, p. 843) has stated in effect that only 64% of patients wearing contact lenses do so without discomfort. We think that this must refer to pre-fenestration days. Since the adoption of this technique the percentage has risen considerably, and one of us, who could wear closed contact lenses for only an hour or so, can wear a perforated pair for ten hours or longer. This, we believe, is the usual experience. The rationale of fenestration was explained by Dr. J. Dallos in the *British Journal of Ophthalmology*, 1946, 30, 607.—We are, etc.,

London, W.1.

### POINTS FROM LETTERS

#### Unclean Hairdressers

AURELIA writes: Can nothing be done about the low standard of cleanliness in our post-war hairdressing establishments? I do not know what is done in the barbers' shops, but every time I have my hair done I am shocked at the lack of the most elementary sanitary precautions. The fact that I take my own comb is regarded with disfavour by the assistant, but if I do not do so a seemingly unclean comb emerges from her pocket, the pre-war jars of disinfectant being no longer used. When the hair is dried, a dirty-looking net is taken from a grimy box full of nets, clips, pins, etc., and a much-used wad of cotton-wool is placed over one's ears. I shudder to think of the diseases that can, and probably are, conveyed in this way. It is almost as alarming as the elementary way in which cups and saucers and so forth are washed up in restaurants and trains.

#### Geriatric Department

Mr. L. Z. COSIN (Orsett Lodge Hospital, Essex) writes: The synopsis of my article on "Modern Methods in the Care of the Aged" (*Journal*, Nov. 29, p. 870) failed to mention the other specialists required in a geriatric department. I append a complete list: (1) Physician experienced in the treatment and diagnosis of aged patients; (2) psychiatrist; (3) physician experienced in physical medicine; (4) orthopaedic surgeon; (5) genito-urinary surgeon; (6) general surgical service.

#### Snoring

Dr. OSMOND H. BROWN (Guildford, Surrey) writes: As to the horse and cow I am not qualified to speak, but as a close associate of cats for over fifty years I can state as a fact that cats can and frequently do both breathe through the mouth and snore. Other animals in which I have personally observed snoring are dogs, dormice, hedgehogs, parrots, owls, and canaries.

## Obituary

SIR JOHN FRASER, Bt.

K.C.V.O., M.C., M.D., Ch.M., F.R.C.S.Ed.

Sir John Fraser, Principal and Vice-Chancellor of Edinburgh University, was one of Edinburgh's most distinguished graduates and inspiring leaders. He died suddenly on Dec. 1 when leaving a meeting which he had been attending at the Old College, having recently resumed his work after a serious and protracted illness.

John Fraser was born at Tain, Ross-shire, in 1885. He graduated M.B., Ch.B. with honours at Edinburgh in 1907, took the degree of Ch.M. with honours in 1910, and was awarded a gold medal for his M.D. thesis in 1912. He studied in Paris and Freiburg, and under Harold Stiles engaged in research on tuberculosis, particularly tuberculosis of bovine origin. His book, *Tuberculosis of the Bones and Joints in Children*, was published in 1914. During the 1914-18 war he served as a captain in the R.A.M.C., was wounded, and was awarded the M.C. and mentioned in dispatches. On his return to Edinburgh in 1918 he became an extra-mural teacher in surgery, and was appointed surgeon to the Royal Hospital for Sick Children and assistant surgeon to the Edinburgh Royal Infirmary. His *Surgery of Childhood* appeared in 1926. His outstanding qualities as a teacher and surgeon were acknowledged when in 1925 he was appointed to succeed Sir Harold Stiles in the régus chair of clinical surgery at Edinburgh University, a post which he held with distinction until 1944, when he was appointed Principal and Vice-Chancellor of the University. In this capacity, in spite of serious ill health, he took a leading part in plans for integrating the development and extension of the University, and a keen interest in all aspects of university life.

Among his many public appointments he was honorary surgeon in Scotland to His Majesty the King, civilian consultant in surgery to the Royal Navy in Scotland, and consultant adviser to the Secretary of State for Scotland on the organization of hospitals in wartime. In 1937 he was honoured with a knighthood, and he was made a baronet in 1943. At the annual meeting of the British Medical Association in Edinburgh in 1927 he was president of the Section of Diseases of Children, and he was vice-president of the same Section at the centenary meeting in London in 1932.

John Fraser was a born teacher, a lucid speaker, a prolific writer, and a master of the art of demonstration. His clinics were popular not only with students but also with graduates from many schools. His surgical skill was widely appreciated, and in addition to his hospital work he had a large private surgical practice, which included many doctors and their families. His operative speed and accuracy of technique were exceptional. He was always unruffled and unhurried and inspired great confidence in his patients and devotion in his staff. Besides being a Fellow of the Royal College of Surgeons of Edinburgh since 1910, he was an honorary Fellow of the American College of Surgeons and also of the Royal Australasian College of Surgeons. As a man, he was sparing of himself in his work for others, and all those who were privileged to meet him will remember his unfailing courtesy and kindness and his quiet charm of manner. He is survived by Lady Fraser and a son and daughter.

J.B. writes: By the sudden death of Sir John Fraser his alma mater has lost a wise guide and a sage counsellor at a time when wisdom and vision are more than ever necessary in university affairs, and the rich promise of a memorable principalship must remain unfulfilled. There have been many

arm and eloquent testimonies to the brilliance of his many achievements and to his unique technical and intellectual gifts. There there is no greatness of character, however, there can be a great man; and Sir John possessed in rich measure the qualities of true eminence—a deep spiritual strength, the more so because so devoid of display, and a broad and sensitive humanity. To the young men he gathered round him in the heyday of his distinguished surgical career he was a supreme teacher and an inspiring example. From his lips fell no harsh criticisms or judgments of his contemporaries, for indeed he spoke ill of none. He was devoid of malice, of jealousy, and of envy; all the remarkable energy, the unsurpassed skill, and the exquisite gentleness he possessed he gave freely and fully to his craft. From his mere presence all his patients derived strength and confidence.

As a clinical instructor, even in a university which has never aimed to attract eminent teachers of the highest intellectual rank, he occupied a unique position. His classes and his operating sessions were alike crowded, and he was never too busy or too tired to explain and to demonstrate. For young men he set the best of all examples—that of a great surgical craftsman, superb in his gentleness and dexterity, wide in his knowledge and wise in his judgment. In his theatre there were no harsh words, no frivolous remarks; and his influence on surgical practice in many parts of the world, through the medium of the many thousands who flocked to his clinics, is incalculable. If, as Disraeli said, a great man is one who affects the mind of his generation, then Sir John Fraser was indeed pre-eminent. Something of his inspiration and his outlook, his humanity and his kindness, has been woven into the fabric of many lives. In such a manner the goodness that men do can live after them. If in a cosmopolitan university the great surgical teachers, like Sir John, are clothed in the dignity and heritage of their high calling and serve well its moral and its physical disciplines, they light a beacon which throws its light across the world. Yet his Celtic temperament and his natural humbleness combined to make him a shy, gentle, and retiring man; but to those who chose to breach the barrier of his reserve he offered a rich reward of loyalty and friendship. We who were privileged to work for him would often have liked to show our love for him more than we dared to do; but I think he comprehended more than we thought and his letters often revealed a depth of affection which he could seldom bring himself to show in any other way.

In his home life he was singularly blessed. His wife and he were deeply devoted to each other, and Lady Fraser, to whom our sympathy goes out at this time, played a notable part in a notable career. Those who saw something of them during his recent illnesses were privileged to witness an affectionate understanding which they will not soon forget. This is a personal tribute. Many, like the writer, will to-day mourn the grievous loss of a dear friend, a great surgeon, a good man. The life of Scotland has been nobly enriched by his presence amongst us and saddened by his death.

J. M. G. writes: Sir John Fraser's career was a record of achievement in everything he undertook. He will be remembered as a great surgeon and teacher and for his qualities of character, which endeared him to everyone with whom he came in contact. For nineteen years he upheld and enhanced the reputation of the regius chair of clinical surgery in Edinburgh. When he succeeded Sir Harold Stiles he was truly in the line of the great tradition, for he was the last house-surgeon of Annandale, who had been the colleague and successor of Lister and assistant to Syme. Even as a young house-surgeon Fraser made an impression on his seniors and on all with whom he worked. The late Mr. Dowden foretold a brilliant future for him from the time of their early association in Mr. Annandale's wards. His reputation was finally established when he read his first paper in Edinburgh, at a meeting of the Medico-Chirurgical Society, on tuberculosis of the bones and joints. The suggestion of the president, Sir Montagu Cotterill, that Fraser should be asked to read a further paper on the subject at the next meeting was received with acclamation by all who were present.

With his high sense of duty, which was one of his outstanding qualities, Sir John never spared himself. Few men in our time can have worked harder than he did, or applied themselves

more consistently to whatever task came to hand. With his special knowledge of the diseases of children as a foundation, he became, in the best sense of the term, one of the great general surgeons, highly competent in almost every branch of surgery. His operative technique was simple and straightforward, and was combined with a manual dexterity and a sureness and gentleness of touch which could scarcely be excelled. However busy he was, he always seemed to find time to read widely, not only in his own subject but in general literature. The knowledge and culture which he so readily acquired were always at his command, and were invariably apparent in his teaching and in his writings. Throughout his career Fraser's teaching was outstanding in its appeal to the students and for many years also to an increasing number of graduates.

Sir John received many distinctions and honours, but to the last he remained the same, the most unassuming and approachable of men, deprecating his own accomplishments and generous in acknowledging the efforts of others. In his personal contacts he had a charm peculiarly his own, and it is not surprising that he gained without exception the affection as well as the respect of his colleagues. Throughout his active career the calls on his time and energy seemed to be without limit or end. His advice was constantly sought by colleagues and practitioners on behalf of their patients, for they knew that everything that could be done would be done by him, and the patients themselves intuitively felt the utmost confidence when they were under his care. He served on and presided over innumerable committees, and delivered addresses to medical societies on many occasions in this country and abroad.

The honour of being appointed Principal and Vice-Chancellor of the University of Edinburgh in 1944 was accepted by him with a full sense of the responsibility involved. The burden of this office came at a time when he was tired with the strain of the war years, but without hesitation he entered on his new duties with the same energy and devotion which he had shown throughout his surgical career. A few months after his appointment he suffered an illness during which for a few days he was critically ill. It is at such a time that a man's true nature is revealed. Under the most trying circumstances he never complained, but showed a constant courage and gratitude for the efforts made to help him. It was characteristic of him that in these critical days his thoughts were always for others and never for himself. Shortly before his sudden death Sir John attended a meeting of the Council of the Royal College of Surgeons of Edinburgh. His colleagues rejoiced to see him, apparently stronger and fitter than he had been. He took an active part in the business of the meeting, but a few minutes after they had parted he passed away in the precincts of the university to which he had dedicated the completion of his life's work.

#### W. ROWLEY BRISTOW, F.R.C.S.

Major-General D. C. Monro writes: News of the death of Walter Rowley Bristow has just reached us here in the Middle East. He will be sadly missed in various circles, social, sporting, and professional, in all of which he had numerous friends and admirers and many grateful patients. Although I had met Walter Bristow before his Army appointment and have good reason to remember his hospitality, kindness, and encouragement on those occasions, it was not until he became a member of the War Office Consultants panel, and of the surgical sub-committee of which I was chairman, that I got to know him intimately and had an opportunity to appreciate his sterling qualities. Besides being one of the senior orthopaedic surgeons in Britain, he had an international reputation. I remember well an occasion in 1939 when a deputation consisting of senior orthopaedic surgeons, which included Bristow, McMurray, and Platt, practically demanded to see our D.G., then Lieut.-Gen. Sir William MacArthur. The deputation insisted that the role of orthopaedic surgery in the war surgical organization should receive fuller recognition, and warned us that it would be folly to forget the mistakes and lessons—all of which had received somewhat belated recognition—of the 1914-18 war. They pleaded that the teaching of the late Sir Robert Jones, whose breadth of view and forceful character had been such an influence for good at that time, should not go unheeded. This warning was timely, and that this advice was valuable is evident when the results in the two wars are com-

pared. The attainment of such results was mainly due to the work of the surgeons who treated the fractures, but Bristow, by his amazing energy, his zeal, his personality, and his amicable relations and close association with the leaders in orthopaedics not only in Britain but with the Dominion and the Allied Forces, and by his fatherly interest in the work of all his juniors, played a very considerable part in it all.

Not unnaturally, Bristow and I often toured and inspected together. I learnt much from him during our joint ward inspections. The tedium and strain of many a tour by land or air was relieved by his high spirits, his optimism, and his genial companionship. Between visits to centres, when we could relax for a while, I was never short of an opponent or partner for almost any sort of game. Bristow was a keen fisherman, a good shot, and an all-round sportsman. If the game we played had an element of chance in it, so much the better; and how often his good-natured and witty propaganda chat would turn the scales in his favour. Too often, whether he lost or won, he would insist on paying the forfeit himself, and what a wonderful host he was. If he could not be at home with his wife and family of whom he was so justly proud, or fishing or shooting, Bristow was happiest either at work or pitting his prowess and cunning against an opponent in some form of game.

This was the surgical colleague or teacher we all came to respect and admire. Those who could proudly regard him as a friend, and they were many, loved to call him "Rowley." Among his friends and admirers can be numbered many from the lower walks of life, especially in his own London—grand types of the old retainer class, club porters, head waiters, and even taxi-drivers and "Bobbies." These loved "Mr. Bristow" too, either because of some unobtrusive kindness or help, or because they admired his philosophy of life, his zest for living it, or were naturally attracted by his cheery personality. Because our friend "Rowley" has gone and we miss him, I and my friends of the surgical service in the Army want to pay a humble tribute to his memory. To his family, who are most entitled to our sympathy, we commend his philosophy of life.

Prof. K. H. BOUMAN, of Amsterdam, died at his home on Nov. 8. He had been until recently professor of psychiatry and neurology at Amsterdam University for many years.

Dr. Henry Robinson writes: All those who went with the British Medical Association tour to the Annual Meeting at Melbourne in 1935 will hear with deep regret of the death of Prof. K. H. Bouman. In the previous winter the professor and his wife went for a brief holiday tour to the Canary Islands; through meeting there a member of the Association they formed an ambition to make the world tour with the B.M.A. in the following summer. It was learned that this was feasible if he were elected an honorary member of the Association, about which, in view of his very distinguished academic record, there was no difficulty at all. Accordingly Dr. and Mrs. Bouman joined the party, and in a short space of time became two of its most popular members. Both of them spoke English admirably—practically without any foreign accent in Mrs. Bouman's case. On the return journey they broke the voyage home by remaining for a time in the Dutch East Indies; to visit mental institutions there had been the justification for the leave of absence granted to him by Amsterdam University.

Prof. Bouman was 73 at the time of his death: the name means "farmer," and is etymologically similar to the term "Boer" as used in South Africa. In normal circumstances he would have retired on pension some years ago, but the exigencies of war prevented this, and he carried on steadfastly, though many times threatened with death by the Nazis for refusing to carry out their orders. When, at the end of hostilities, relief should have been in sight it was further postponed because the deputy who had been trained up to succeed him was sent to prison for life on a charge of collaboration. Two years ago, after the liberation, Bouman visited London and delivered an address to the Medico-Psychological Society on the hardships and diseases produced among the population of Holland by the Germans, whose aggression and disregard of human rights he had foreseen long before the war broke out. This account of his privations and those of his compatriots produced a lasting effect upon his hearers, all the more so by reason of the grave composure, dignity, and emphasis, without any ostensible expression of rancour, with which it was delivered. To his widow, Mevrouw Wilhelmina Bouman-Slingenberg, the deep sympathy of her many English friends will surely be extended. There were no children of their marriage.

## Medical Notes in Parliament

### Criminal Justice Bill

Mr. CHUTER EDE on Nov. 27 moved the Second Reading of the Criminal Justice Bill, which was the subject of a leading article in our issue of Nov. 22 (p. 826). Mr. Ede said that the Bill abolished penal servitude and hard labour and also the division of prisoners into first, second, and third divisions. The abolition of penal servitude involved the abolition of the ticket-of-leave system. The Bill proposed to abolish whipping as a punishment to be ordered by the courts. Crimes of violence had increased markedly since 1938 and the Government could not regard the time as opportune for the inclusion in the Bill of a provision for the suspension or abolition of the death penalty. The Government would put their case before the House, but no attempt would be made to coerce the conscience of any member.

Mr. ALLEN noted that there was nothing in the Bill to provide for payment for inquiry by an expert into the mental condition of a child or adult. Viscountess DAVIDSON also remarked that the Bill did not make mention of educational psychologists.

Mr. GAGE asked that allegedly insane people should be given legal aid in the lower court. Dr. MORGAN did not agree. He said that if prisoners were insane or mentally defective what was required was a report by a psychiatrist. Mr. GALLACHER condemned the silent cell and said he had heard prisoners battering against the door night after night. There was no more exquisite torture.

When the debate was resumed on Nov. 28 Mrs. CORBET said that in one prison sick persons were obliged, however ill they were, to get up at 5 a.m. to consult the doctor. Mr. JENNER said the McNaghten rules were laid down some hundred years ago, and the judges found themselves to-day bound to observe rules which in the opinion of most people concerned were antiquated. The hanging of persons subject to attacks of epilepsy could be altered by having a proper record of an accused man's past. To-day in the prisons the man might be put under observation by a medical officer who had no knowledge of investigating mental deficiency.

Replying for the Government Mr. YOUNGER said that where it was practicable an inquiry into the physical and mental condition of an offender would take place in any institution and not necessarily in a remand centre. Medical personnel would be provided under the National Health Service, but how far it would be possible to provide enough skilled medical officers, psychiatrists, and psychologists no one in the House could say. Mr. EDE promised to see whether an extra half-day could be given for debating the Bill during the Report Stage, and the measure was read a second time without a division.

### Purchase Tax on Drugs

When the Autumn Finance Bill was taken in Committee on Dec. 2 Mr. SELWYN LLOYD moved to exclude from the increase in purchase tax drugs and medicines, manufactured or prepared. This point was discussed in an annotation in our issue of Nov. 22 (p. 829).

Mr. Lloyd said that at the moment drugs and medicines were subject to a tax of one-sixth of the wholesale value of the goods, which was now to become one-third. The matter had been dealt with on the last Finance Act. When Mr. Stanley spoke on that occasion he got a promise from the Financial Secretary to the Treasury that during the twelve months after June 17, 1947, the date of that debate, he would look into the matter of drugs and medicines and examine the illogicalities which he admitted to exist. The present was a convenient moment to make a progress report on how far the Financial Secretary had gone. Mr. Selwyn Lloyd went on to say that he had attempted to find out which drugs and medicines were subject to purchase tax. Iodine—a simple medicine very commonly used—was subject to tax. He was surprised that a Government so prone to make cuts should be keen on doubling the tax on a simple antiseptic.

Sir HENRY MORRIS-JONES said some drugs subject to the double tax were a great help in combating sleeplessness. Mr. ERROLL said many of the old and infirm needed medicines and drugs from time to time and the extra purchase tax represented a serious addition to their weekly budget. He reminded the House that the Purchase Tax (Exemption) Order, 1945, exempted penicillin, the sulphonamides, vaccines, and morphine. Parliament taxed the curing of toxic goitre but left free the curing of pneumonia. Matters should be arranged so that all important diseases could be cured without the tax.

## The HECSON

SUPER ELASTIC TRUSS

for the Treatment of Hernia

Strap is fixed to Pad at A. Therefore greater pressure is exerted at B, when the strap is pulled tightly.

Where treatment of Hernia by surgical methods is undesirable 'or any reasons, the HECSON super elastic truss can be confidently recommended. The Special Feature of the HECSON Truss is that the perineal or under strap is attached to the top of the pad instead of the lower margin as in the ordinary elastic or old spring truss. Thus it becomes part of the leverage mechanism for increasing the pressure of the pad at its base.

Price: Single £12s. 6d.  
Double £13s. 6d.

## The Delicious Nourishing, Energising Vitamin Food

for Infants, Children & Adults  
—at all Seasons

BY presenting valuable nutritive elements and important vitamins in a delicious form, 'Vimaltol' offers special advantages in everyday practice to the physician. With its delightfully sweet orange flavour 'Vimaltol' is readily acceptable to every patient.

'Vimaltol' is made from specially prepared malt extract of high protein content, yeast—one of the richest sources of Vitamin B<sub>1</sub>—and Halibut Liver Oil, an important source of Vitamins A and D. It is also fortified with additional vitamins and mineral salts, and is deliciously flavoured with orange juice.

'Vimaltol' is standardised to contain in each fluid ounce: 648 international units of vitamin A and 1390 of vitamin D; also 0.3 milligrammes of vitamin B<sub>1</sub>, 4 of Niacin (P.P. vitamin), and 4.8 of Iron, in a readily assimilated form.

'Vimaltol' has, therefore, an important therapeutic value where the deficiency of certain essential food elements in the dietary has resulted in abnormal conditions. Its regular use assists the development of the growing organism and the maintenance of correct metabolism while raising the general resistance against infection.

'Vimaltol' can be prescribed with advantage at all seasons, and for patients of all ages.

ate of purchase tax being imposed on the necessary drugs and medicines. The dispensing practitioner who made up medicines or the use of his patients received a certain fixed rate for such medicines; he must bear entirely the cost of the ingredients or these medicines.

Mr. LINSTEAD asked the Chancellor to have a look at the whole operation of the purchase tax as it affected medicine. When the subject was first discussed in the House Mr. Dalton indicated that he could not afford the loss of revenue which the omission of the tax would entail. There was machinery or exempting costly and essential drugs from the tax, but that machinery had been used in a very restrained way. If the Chancellor imposed additional taxation on patent medicines there might be a good deal of sympathy with him. If he desired to do that this was the opportunity for the whole question of the taxation of medicine to be examined.

Sir STAFFORD CRIPPS said there was a long list of exempted drugs which had been dealt with in 1945. The extension of that list to get it on a sounder and better basis had for some time been discussed with the Ministry of Health. He admitted that the present basis did not seem to be wholly logical. This was a matter which between now and next April should be re-examined to exclude those drugs of real importance. By the definition of the Finance Act, 1940, medicines that were made up by a chemist did not attract the tax as a manufactured article, though some drugs in the medicine might be taxed. The incidence was not very heavy, and at present the tax affected what used to be known as patent medicines. Much the majority of the receipts from this tax were really in substitution for the old Medicine Stamp Duty.

Sir Stafford could not believe that the taking of patent medicines without the advice of a doctor was a good way of dealing with the health of any population. It was not always known whether these medicines would accomplish the ends which they were advertised to accomplish, or indeed any ends at all. The Committee could take it that when the list came to be properly considered the bulk of the increase in taxation would fall on goods which used to be subject to stamp duty. Before April he would look into the matter to see whether there could not be more logical and better arrangements about exemptions. They would be much assisted in this matter because the new Health Service Act would be coming into operation. The Ministry of Health would be large users in hospitals and in connexion with other matters.

Mr. PITMAN said that if the Chancellor was going to look at this list he could act quite apart from Budget day and change the list at any minute. If he could not do that now let him look at the grants to doctors under the Health Acts, because grants for the doctors were low enough as it was.

Mr. LINSTEAD said medicines which were prescribed by doctors would in fact attract the tax in so far as they were proprietary medicines. If they set aside medicines prescribed under the National Health Insurance Act, 50% of those prescribed to-day were proprietary medicines which would attract the full 33½% tax. The old stamp duty did not apply to medicines which were sent to the chemist to be sent out with a medical prescription. Therefore they would have a heavy tax on medicines which previously had not borne any tax at all.

The amendment moved by Mr. Selwyn Lloyd was defeated by 278 to 131.

## Medico-Legal

### A BROKEN SURGICAL NEEDLE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

In a case recently heard at the Liverpool Assizes the question was raised how far it may be the duty of a doctor to press his advice on a reluctant patient. The doctor was repairing a perineal laceration, sustained during childbirth on Oct. 24, 1945, in a girl of 18, when the needle broke and part of it remained imbedded in the tissues. He telephoned for advice to a gynaecologist, who expressed the opinion that the fragment should be left until after she had recovered from the effects of the delivery, and then removed if it had not already been extruded. Fifteen days later the patient complained of discomfort and was advised by the doctor to return in two days, on Nov. 12, to see his wife, also a doctor. This appointment was kept by the patient, but the doctor had forgotten to inform his wife, and made another appointment. The patient attended again, but, according to a Press report, "after sitting in the

waiting-room for some time she gathered the impression" that the lady doctor was not available, and so went home, thinking that the doctor had "lost interest" in her case. She did not attend again "because of her shyness" until ten months later, and then only because she was urged to do so by her mother-in-law. She was then admitted to hospital and had the fragment removed. The Court held, on these facts, that the doctor had been negligent, and awarded £75 damages. A stay of execution was granted. The doctor stated in evidence that, when the patient failed to keep her appointment to see his wife, he assumed that she must have gone direct to the surgeon, or changed her doctor.

It was urged for the defence that it was no part of the doctor's duty to "chase the patient," but Mr. Justice Streatfield said, "She was rather shy, timid, and, I think, a little nervous. It was not going to be a serious operation to have the needle removed, but she was afraid it was. The doctor should have reassured her. He made one appointment for her to see a woman doctor, but forgot to make the necessary arrangements. The doctor let the matter slide, did not make sure the needle was removed, and so was guilty of a breach of duty to the patient." Evidence was given at the hearing by a lecturer in pathology at the local university, who said that "the breaking of a needle could easily occur," and that if this happened it was the duty of a doctor to seek "the co-operation of a surgeon to have the needle removed."

It was not suggested that the breaking of the needle was any evidence of negligence, and the doctor did in fact seek, and follow, the advice of a surgeon as to the proper steps to be taken to deal with the imbedded fragment. Where he failed, in the view of the Court, was in that he did not go far enough in his efforts to persuade a timid and reluctant patient to undergo a minor operation. While it would not be practicable to ascertain in every case why a patient fails to keep an appointment or to act on the advice given, this case illustrates the danger of assuming that such a patient needs no further attention.

## Universities and Colleges

### UNIVERSITY OF OXFORD

In a Congregation held on Nov. 22 the following degrees were conferred:

D.M.—D. M. T. Gairdner (in absence).

B.M.—D. M. L. Doran.

### UNIVERSITY OF LONDON

Noel Francis MacLagan, M.D., D.Sc., M.R.C.P., F.R.I.C., has been appointed to the University Chair of Chemical Pathology tenable at Westminster Hospital Medical School from Oct. 1.

### UNIVERSITY OF DUBLIN

Joseph Warwick Bigger, M.D., F.R.C.P., professor of bacteriology and preventive medicine and dean of the Faculty of Physic, University of Dublin, was elected to the Senate on Nov. 20, to fill the vacancy created by the resignation of Mr. Justice Kingsmill Moore.

### SCHOOL OF PHYSIC, TRINITY COLLEGE

The following medical degrees were conferred on Dec. 3:

M.B., B.Ch., B.A.O.—K. Adler, C. L. S. Archer, Irene R. Christie, R. F. E. Coolican, Kathleen P. E. Crawford, S. Davis, J. R. Evans, Katherine S. P. Hill, Margaret W. Lamb, D. E. Mellon, T. J. Mills, P. R. Oliver, Irene S. Orgel, J. R. F. Smith, F. E. Williams, R. J. York.

M.A.O.—J. A. O'N. Mulcahy.

### UNIVERSITY OF WALES

The following candidates for the degrees of M.B., B.Ch. at the Welsh National School of Medicine have satisfied the examiners at the examinations indicated:

MEDICINE.—H. B. Davies, T. Griffiths, H. Harrop-Griffiths, T. R. Hunt, Dilly W. John, H. E. Jones, Margaret E. B. Jones, Margaret O. Jones, J. B. R. Lewis, Constance A. M. Llewellyn, Myfanwy M. G. Prethero, G. G. Richmond, Prudence K. Roberts, Mary Smith, T. M. Warren.

PHARMACOLOGY.—Josephine J. Candy, M. L. Castell, R. B. Davies, B. M. Frost Smith, B. J. Fudge, S. G. Gang, A. R. Harris, Mary E. V. Jones, Margaret Pugh, J. A. E. Richards, D. B. Scourfield, T. B. Stephens, S. Thomas.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Faculty held on Dec. 1 with the President, Prof. G. B. Fleming, in the chair, Graham Herbert Anderson, M.B., Ch.B. (Glasgow), Edward Kenyon Blackburn, M.D. (Sheffield),

Samuel Dunn, M.D. (Glasgow), Rankine Good, M.D. (Shotts), Arthur Thomson Hendry, M.B., Ch.B. (Giffnock), James Hood, M.B., Ch.B. (Lancaster), William Macfarlane Lancaster, M.B., Ch.B. (Glasgow), Thomas Davidson Veitch Lawrie, M.B., Ch.B. (Glasgow), George McCracken, L.R.C.P.&S.Ed., L.R.F.P.S. (Shirlett), Alastair Gould Macgregor, M.B., Ch.B. (Bearsden), Robert Montgomery, M.B., Ch.B. (Rutherglen), Archibald Walker Sloan, M.B., Ch.B. (Bearsden), and George Will, M.B., Ch.B. (Glasgow) were admitted Fellows *qua* physician; John Cuthbertson Jeffrey, M.B., Ch.B. (Glasgow), Alexander Macpherson Keith, M.B., Ch.B. (Glasgow), Shreedhar Shreenivas Kirtane, M.B., B.S. (Edinburgh) Andrew Bruce MacLean, M.B., Ch.B. (Glasgow), Norman McSwan, M.B., Ch.B. (Kilmalcolm), William Albert Watt Maney, L.R.C.P.&S.Ed., L.R.F.P.S. (Glasgow), Purushottam Bhagwant Sulakhe, M.B., B.S. (Glasgow), Andrew Tomney, M.B., Ch.B. (Glasgow), William Arthur Leigh Tucker, L.R.C.P.&S.Ed., L.R.F.P.S. (London), and Stuart Young, M.B., Ch.B. (Glasgow) were admitted Fellows *qua* surgeon.

## EPIDEMIOLOGICAL NOTES

### Poliomyelitis

The more rapid decline in notifications mentioned last week has been maintained. Notifications of poliomyelitis for the week ended Nov. 29 were 103 (142) and of polio-encephalitis 3 (3). The figures in parentheses are those for the week ended Nov. 22. It has several times been suggested in these notes that the original notifications tend to overstate the actual incidence of cases in epidemic periods because of the difficulty of diagnosis in the early stages and the desire of practitioners to secure early treatment for their patients. Figures for poliomyelitis recently supplied by the General Register Office for the June and September quarters confirm this view.

Notifications	Original	Corrected
June quarter .. .. .	268	244
September quarter .. .. .	6,192	5,077

### Discussion of Table

In *England and Wales* infectious diseases were less prevalent during the week. Decreases were recorded in the incidence of scarlet fever 135, measles 122, acute pneumonia 79, acute poliomyelitis 44, whooping-cough 34, and cerebrospinal fever 10; the only increases were in the notifications of dysentery 46 and diphtheria 25.

A small decline in scarlet fever occurred throughout the country. Although the total notifications of whooping-cough declined, an increased incidence was recorded for London and the south-east region 65, the south midland region 45, and Lancashire 41. The largest local variations in the trend of cases were increases in Northamptonshire 63, and Lancashire 63. The rise in the incidence of diphtheria was due to a small general increase.

There were 48 cases of dysentery notified in Berkshire, 13 from Reading C.B., and 35 from Wallingford R.D., where cases reappeared after a lapse of one week. An outbreak involving 18 persons was recorded in Staffordshire, Willenhall R.D. The only other large return for dysentery was Lancashire 20.

The incidence of poliomyelitis, which has been falling since the first week in September, decreased by 44 cases. The largest returns were Lancashire 16, London 13, Middlesex 12, and Yorkshire West Riding 10.

In *Scotland* the incidence of infectious diseases declined. There were decreases in the notifications of scarlet fever 42, measles 46, acute primary pneumonia 29, and diphtheria 14. The only exception to the general downward trend was a rise of 7 in the notifications of poliomyelitis contributed by the western area.

In *Eire* the only variations of any size in the returns of infectious diseases were decreases in the notifications of measles 19 and diarrhoea and enteritis 14. Only 8 cases of measles were notified in Wicklow, Bray U.D., where 78 cases were reported in the preceding week. An increase in the notifications of measles was reported from Dublin C.B. 18, Roscommon, Boyle R.D. No. 1, 14, and Waterford, Dungarvan U.D. 43.

### Week Ending November 29

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 1,765, whooping-cough 1,513, diphtheria 216, measles 2,772, acute pneumonia 567, cerebrospinal fever 44, acute poliomyelitis 103, dysentery 77, paratyphoid 18, typhoid fever 8.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov. 22.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of the 126 great towns in (a) The 126 great towns in (b) London (administrative county). The 13 principal towns in Eire. (c) ...

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

## Medical News

### Dr. Charles Bolton, C.B.E., F.R.S., F.R.C.P.

We announce with regret the death, on Dec. 6, of Dr. Charles Bolton, C.B.E., F.R.S., F.R.C.P., consulting physician to University College Hospital and Fellow of University College, London.

### Moray Lodge Sick Bay

A sick bay was opened on Dec. 4 at Moray Lodge, Campden Hill, Kensington, London, W., for civil servants of the lower-paid groups who are appointed to posts in the London area and who live in hostels or lodgings. The sick bay will be administered by the Ministry of Health; the British Red Cross Society will be responsible for its day-to-day management; and the Treasury Medical Adviser and his staff will act as medical officers. While private doctors will be free to visit their patients in the sick bay this will not always be necessary since medical officers will be available on the spot. No case of serious or notifiable infectious disease will be accepted at the sick bay, its function being to deal with the "home nursing" type of case only.

### Common Cold Research

More volunteers are required for the experiments which for the past eighteen months have been conducted by the Common Cold Research Unit set up at the Harvard Hospital, Salisbury, by the Medical Research Council and the Ministry of Health. It was emphasized when the investigations started that dramatic results could not be expected, but the work is making steady progress. It has been established that the virus is about the size of the influenza virus, and that it can withstand freezing at temperatures as low as  $-70^{\circ}\text{C}$ . Attempts to grow the virus in the laboratory have so far proved unsuccessful. Ten-day sessions for which volunteers are required next year are the periods beginning Jan. 14 and 28, Feb. 11 and 25, March 10, April 14 and 28, May 26, and June 9. People of either sex between the ages of 18 and 40 are wanted, and full details may be obtained from the Medical Officer, Harvard Hospital, Coombe Road, Salisbury.

### British Association of Allergists

At a meeting held at Oxford on Nov. 15, it was decided to form a British Association of Allergists. The first general meeting of the association will be held at St. Mary's Hospital, Paddington, London, W., on Saturday, Jan. 24, when the speakers will include Dr. John Freeman and Mr. Frank Coke. Further particulars of the association may be obtained from the secretary (Dr. A. W. Frankland), The Wright-Fleming Institute of Microbiology, St. Mary's Hospital, Paddington, London, W.2.

### Yorkshire Society of Anaesthetists

The Yorkshire Society of Anaesthetists has been formed with the object of promoting fellowship and scientific advance in the subject, and an inaugural meeting was held recently at Leeds, under the presidency of Dr. S. T. Rowling. Any doctor who is interested in the society and who did not know of the first meeting should write for particulars to the honorary secretary, Dr. R. C. Lawrence, 6, Wedgewood Grove, Roundhay, Leeds, 8.

### Tuberculosis Fellowships

The National Jewish Hospital at Denver announces that Fellowships for postgraduate study in tuberculosis and allied diseases will be granted for three-months, six-months, or one-year periods. Information regarding the Fellowships can be obtained from Dr. Edgar Mayer, chairman of the National Medical Advisory Board, National Jewish Hospital at Denver, 470, Park Avenue, New York, N.Y., or Dr. Allan Hurst, medical director, National Jewish Hospital at Denver, 3,800, East Colfax Avenue, Denver 6, Colorado, U.S.A.

### Unification of Pharmacopoeias

The first meeting of the Expert Committee on the Unification of Pharmacopoeias—a committee of the World Health Organization—was held at Geneva on Oct. 13-17. Dr. C. H. Hampshire (Great Britain) was elected chairman. The intention is to produce an international pharmacopoeia whose scope in the first place would be limited to drugs considered essential in medical practice, and 244 drugs were selected from a list of 534 for immediate attention. The preparation of draft monographs and the carrying out of research were allocated among the members present. In view of the amount of work required the Committee recommended that at least three additional members be appointed and that a unified secretariat should be formed.

### William Gibson Research Scholarship

The Royal Society of Medicine has awarded the William Gibson Research Scholarship to Dr. Alice Palmer, of Sydney, Australia, for her proposed research on the circulation in pregnancy.

### Colony of Aden

Edgar Cochran, M.D., has been appointed a member of the Executive Council of the Colony of Aden.

### Change of Address

Messrs. Burroughs Wellcome and Co. announce that from Dec. 15 the address of their Home Division will be 183-193, Euston Road, London, N.W.1 (Telephone: Euston 4477). The same address will apply to their Overseas Division from Dec. 21.

### Wills

Dr. Walter Dickson, Ealing, W., who died on July 6, left £67,039; he left £500 to the Royal Medical Benevolent Fund. Dr. John Alexander Neilan, for some years M.O.H. for Seaham, left £6,208. Dr. Phillip William McCrea, of Bristol, who died intestate, left £178. Dr. Edward Theodore Withington, of Oxford, the well-known medical historian, who died on April 20, left £20,552; he left £100 to the Royal Medical Benevolent Fund.

## COMING EVENTS

### Royal Microscopical Society

A meeting of the Royal Microscopical Society will be held at B.M.A. House, Tavistock Square, London, W.C., on Wednesday, Dec. 17, at 5.30 p.m., when Mr. Basil Wright, president of the Scientific Film Association, will describe the aims and objects of the association; Mr. A. F. W. Hughes will show films, including "Tissue Culture by Phase-Contrast"; and Dr. Adrianus Pijper's film "Shape and Mobility of Bacteria" will be exhibited.

### Bearsted Memorial Hospital

The opening ceremony of the new building of the Bearsted Memorial Hospital in Lordship Road, Stoke Newington, London, N., will be performed by Viscountess Bearsted, president of the hospital, on Wednesday, Dec. 17, at 3 p.m. The hospital is open to patients irrespective of race or creed, and emergency cases and abnormalities may be referred to the board for admission and ante-natal treatment by the hospital's consultant obstetric staff.

### Pan-American Association of Ophthalmology

The Third Pan-American Congress of Ophthalmology will be held at Havana, Cuba, from Jan. 4 to 10, 1948, when it is anticipated that about 1,000 eye specialists will attend the sessions at the University of Havana School of Medicine. A programme of more than forty formal papers has been arranged, with speakers divided about equally between physicians of the northern half of the hemisphere and those of the Latin-American countries. In addition to the contributions by members there will be several by specially invited guests, including Sir Stewart Duke-Elder (London), who will speak on "Penicillin in Ophthalmology," and Dr. Elizabeth Cass (Gibraltar), who will discuss strabismus.

## SOCIETIES AND LECTURES

### ROYAL SOCIETY OF MEDICINE -

General Meeting of Fellows.—Tuesday, Dec. 16, 5.30 p.m. Ballot for election to the Fellowship.

Section of Pathology.—Tuesday, Dec. 16, 8.15 p.m. Communications by Dr. A. Glücksman: Quantitative Histological Examinations of Serial Biopsies in Relation to the Radiotherapy of Epithelial Tumours. Dr. G. Payling Wright: The Action of Tetanus Toxin on the Rabbit Iris. Dr. J. Holborow: Effects of Penicillin on the Nasopharyngeal Flora.

Section of Dermatology.—Thursday, Dec. 18, 5 p.m. (Cases at 4 p.m.)

Section of Obstetrics and Gynaecology.—Friday, Dec. 19, 8 p.m. Discussion: Urological Problems in Gynaecological Surgery, with Special Reference to the Vesicovaginal Fistula and the Divided Ureter. Openers: Mr. Everard Williams, Miss Catherine Lewis, and Mr. Ogier Ward.

EDINBURGH CLINICAL CLUB.—At B.M.A. Scottish House, 7, Drumheugh Gardens, Edinburgh. Thursday, Dec. 18, 8 p.m. Dr. H. M. Traquair: The Lazy Eye. A discussion will follow.

EUGENICS SOCIETY.—At Royal Society's Rooms, Burlington House, Piccadilly, London, W., Tuesday, Dec. 16, 5.30 p.m. Dr. J. A. Fraser Roberts and Dr. Eliot Slater: Genetics, Medicine, and Practical Eugenics. All interested in the subject are invited to attend.

**HUNTERIAN SOCIETY.**—At Talbot Restaurant, London Wall, E.C., Monday, Dec. 15, 7 for 7.30 p.m. Dinner-meeting. Discussion: Menstrual Disorders in Relation to General Medicine. To be opened by Mr. Aleck Bourne, Dr. Edward Sharp, and Mr. John Howkins.

**ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE**, 28, Portland Place, London, W.—Monday, Tuesday, and Wednesday, Dec. 15, 16, and 17, 3 p.m. Harben Lectures by Prof. E. D. Adrian, O.M., M.D., F.R.S., F.R.C.P.: The Organization of the Nervous System.

### POSTGRADUATE DIARY

**LONDON CHEST HOSPITAL**, Victoria Park, E.—Friday, Dec. 12, 6 p.m. Mr. S. C. Suggit: Common Lesions of the Glottis. (*Change of lecturer and subject.*) Friday, Dec. 19, 5 p.m. Dr. Franklin Wood: X-ray Kymography of the Heart and Lungs.

**LONDON SCHOOL OF DERMATOLOGY**, 5, Lisle Street, Leicester Square, W.C.—Tuesday, Dec. 16, 5 p.m. Dr. J. E. M. Wigley: The Pemphigus Group of Eruptions.

A two-months postgraduate course in surgery will be held at the Royal College of Surgeons in Ireland starting on April 12, 1948. The number of students is limited to 30 and the fee is 20 guineas. Students may enrol now with the Registrar, Royal College of Surgeons, St. Stephen's Green, Dublin.

### APPOINTMENTS

**LONDON COUNTY COUNCIL.**—The following appointments have been made in the Council's mental health services at the hospitals indicated in parentheses: *Physician Deputy Superintendents*, J. C. Batt, M.D., M.R.C.P., D.P.M. (St. Ebba's); D. Shaw, M.D., M.R.C.P., D.P.M. (Sutton Emergency).

### BIRTHS, MARRIAGES, AND DEATHS

#### BIRTHS

**Jermitt.**—On Nov. 28, 1947, at King's College Hospital, Denmark Hill, S.E., to Mary, wife of Dr. E. W. Jarratt, a son.

**Morles.**—On Nov. 22, 1947, at Albion House, Faversham, to Joan (*née* Cannon, M.B., Ch.B.), wife of Dr. Alexander Mories, a daughter.

**Petit.**—On Nov. 28, 1947, to Joan Lamplugh, M.B., Ch.B., wife of Joseph Petit, of Tanganyika, a daughter—Anne.

**Shaw.**—On Nov. 21, 1947, at Grove House Nursing Home, Norwich, to Jean (*née* Harri), wife of Richard E. Shaw, F.R.C.S., a son.

**Todd.**—On Nov. 28, 1947, at the Private Hospital, Leicester, to Eileen (*née* Gilbert), wife of R. McLaren Todd, M.D., M.R.C.P., a son—Hugh Ronald McLaren.

**Trussell.**—On Nov. 29, 1947, at South London Hospital, to Lily (*née* Chant, B.Sc.), wife of Sq.-Ldr. R. R. Trussell, R.A.F.V.R., a daughter.

**Zaki.**—On Nov. 30, 1947, at Private Clinic Nursing Home, 35, Drumsheugh Gardens, Edinburgh, to Irene (*née* Hope), wife of Dr. Y. E. Zaki, a son—Stuart Swinton.

#### DEATHS

**Bolton.**—On Dec. 6, 1947, in London. Charles Bolton, C.B.E., D.Sc., M.D., F.R.C.P., F.R.S.

**Downton.**—On Dec. 2, 1947, at Hornsey Central Hospital, Arthur Sydney Downton, M.R.C.S., L.R.C.P., aged 68.

**Fleming.**—On Dec. 5, 1947, at Innerhaven, Kintloch Rannoch, Robert Alexander Fleming, LL.D., M.D., F.R.C.P., F.R.S.Ed., Surgeon, H.M. The King's Bodyguard for Scotland.

**Forbes.**—On Nov. 27, 1947, at 9, Albany Terrace, Aberdeen, Charles Forbes, O.B.E., M.B., Ch.B.

**Fraser.**—On Dec. 1, 1947, Sir John Fraser, Bt., K.C.V.O., M.C., LL.D., M.D., F.R.C.S.Ed., Principal and Vice-Chancellor, University of Edinburgh.

**Hearry.**—On Dec. 8, 1947, at 8, Ravenslea Road, London, S.W., Patrick Nicholas Hearry, L.R.C.P.I.&L.M.

**Howard.**—On Nov. 26, 1947, outside his home, "Pleasance," Beaumont Rise, Marlow, Bucks, Robert Howard, M.B.E., M.D., aged 75.

**Jackson.**—On Dec. 1, 1947, after an accident, at Manchester Royal Infirmary, William Ferriaday Jackson, M.B., Ch.B., aged 74.

**Lacey.**—On Nov. 29, 1947, at Capetown, Bernard Warner Lacey, M.B., B.S., of 181, Herbert Road, Woolwich, S.E.

**Mason.**—On Dec. 7, 1947, at Southdown, the Shrubberies, South Woodford, E., Hamish Falconer Mason, F.R.C.S.Ed.

**Moffat.**—On Nov. 15, 1947, at Bulawayo, S. Rhodesia, Robert Unwin Moffat, C.M.G., M.D., Colonial Medical Service, retired.

**Moore.**—At "Blairfinde," Greystones, Co. Wicklow, George Peirce Moore, M.D., aged 77.

**Scott.**—On Nov. 20, 1947, at 13, Southernhay West, Exeter, Robert Scott, M.B., Ch.B.

**Smith.**—On Dec. 6, 1947, at "Marlburg," Chipping Norton, Oxon, Thomas St. Clair Smith, M.B., aged 71.

**Thomson.**—On Dec. 2, 1947, at 83, Duke Street, London, W., William Brown Thomson, M.D., aged 68.

**Young.**—On Nov. 20, 1947, John Miller Young, M.C., M.B., D.P.H., aged 56.

## Any Questions?

### Diet in Pre-eclampsia

**Q.**—What are the essential features of the diet in cases of albuminuria of pregnancy?

**A.**—It is assumed that the term "albuminuria of pregnancy" is used to mean pre-eclampsia. Although it is possible to make some general observations on diet in this disease, each case deserves individual consideration. Starvation should be avoided, except perhaps for short periods in severe cases when eclampsia is threatening. Overeating also should be discouraged and the total intake should be average, bearing in mind that the patient is confined to bed—say 2,000 calories a day. Carbohydrate foodstuffs should be given freely, in the form of glucose if necessary. Fats should be taken in moderate amounts only. The traditional low-protein diet is fast losing favour. There is, perhaps, something to be said for limiting the intake of red meat, but other protein foods—milk, eggs, etc.—should be encouraged. Indeed in some cases in which oedema is associated with hypoproteinaemia large amounts of protein are required. Vitamins A, B complex, C, D, and possibly E are important, and if the diet is not rich in these they can be given in the form of supplementary concentrates. A good supply of calcium is also desirable. Table salt should be excluded from the diet so far as possible, and this means excluding food cooked or preserved in salt. The harmful ion is sodium, and care is necessary to see that the patient does not take this in any other form—for example, mixtures given for indigestion. The intake of fluid is also important, particularly if it is impossible to exclude sodium from the diet completely and if oedema is a prominent feature of the case. In such cases the amount of fluid permissible can be gauged roughly by the output of urine during the previous twenty-four hours, and should not exceed this.

Dietetic restrictions (except in respect of fluid and salt) at present play a relatively unimportant part in the treatment of pre-eclampsia, and the emphasis is on rest in bed. With the present system of rationing in force there is little danger of overeating, and most patients can safely be told to eat their full allowance of all foodstuffs.

### Prevention of Venereal Disease

**Q.**—Is the application of penicillin ointment to the glans penis and meatus after sexual intercourse a certain preventive of venereal disease?

**A.**—The answer is in the negative. Penicillin cream applied immediately after sexual intercourse would probably destroy all or most of any spirochaetes or gonococci on the surface, but might not reach organisms which had penetrated into the tissues; naturally it would not protect against those forms of V.D. the organisms of which are not susceptible to penicillin. It seems doubtful whether penicillin applied locally would be any more effective in preventing the development of V.D. than any other ordinary hygienic measures, such as thorough washing with soap and water or bathing with mild antiseptics. In all probability gonococci penetrate some distance into the male urethra during sexual intercourse and so would be out of reach of local applications other than irrigating fluids. There is no certain preventive of venereal disease except the avoidance of any possible contact with the various causal organisms.

### "Privileged Communications"

**Q.**—(a) In the middle of 1946 two women came to Hore. One of them retired to bed, and was examined by her own doctor the next day. In view of the possible legal proceedings the uninjured person called in a second doctor, who, at the request of the first doctor and with the patient's consent, examined the latter and was paid a fee. Twelve months later the solicitor for the defendant (uninjured person) applied to the second doctor for a detailed report of his examination of the plaintiff ("injured" party). Should a report be forwarded to the solicitor?

(b) After the death of a patient from urogenital infection an insurance agent asked for a report on the patient's condition.

history, as only two years previously the man had been insured, without medical examination, by a relative, and the company felt this early claim needed investigation. Would a report under these circumstances be regarded as a "privileged communication"?

A.—(a) It is quite in order for the second doctor to send a report to the defendant's solicitor. The patient, in giving consent to an examination by the second doctor, and presumably knowing that he was acting on behalf of the defendant (otherwise this consent would be invalid), has given an implied consent to the communication of the results of the examination to the defendant and also to the defendant's solicitor. Such a report is privileged—that is, if given *bona fide* (without "malice") it will not be held to be defamatory of the plaintiff.

(b) The doctor should not send any report to the insurance company without the written consent of the deceased patient's executors (if he made a will) or administrators (if he did not). In order that such consent should be valid they should be fully informed of the circumstances so that they understand that the insurance company is seeking grounds to repudiate the policy for non-disclosure. Provided the doctor obtains such consent his report will be a privileged communication.

### Raspberry-leaf Tea

Q.—Many midwives tell their antenatal patients to drink raspberry-leaf tea. Is it any good, and if so in what way?

A.—Raspberry-leaf tea has long been used as a herbal remedy to allay labour pains and relieve dysmenorrhoea. In 1941 Burn and Withell (*Lancet*, 1, 1) showed that extracts of raspberry leaves contain a substance—fragarine—that relaxes the uterine muscle of the non-pregnant cat. A relaxing action on the human pregnant uterus was demonstrated by Sir Beckwith Whitehouse (*B.M.J.*, 1941, 2, 370). Crude raspberry-leaf tea was used at about the same time in a Worcestershire maternity hospital, but no results were ever published. Since then little has been heard of this concoction. The dose usually recommended is 10 to 20 oz. (28–56 ml.) of a 5% infusion of dried leaves in hot water. It is difficult to see how relaxation of the uterus will help a normal labour, unless the active principle in raspberry leaves acts mainly on the os and the lower segment. Conceivably it might have some application in the management of abnormal labour due to a rigid cervix or excessive uterine contraction, and in the treatment of spasmodic dysmenorrhoea.

### Absorption of Liquid Paraffin

Q.—Am I right in thinking that, though ordinary medicinal paraffin is not absorbed, when it is emulsified it is absorbed by the villi and laid down in the fat stores, whence it cannot again be mobilized, and that consequently the giving of paraffin emulsion as a laxative is unwise?

A.—Liquid paraffin can pass through the intestinal wall of the rat if very finely emulsified, oil globules of a diameter greater than 0.5  $\mu$  not being absorbed. The oil is then carried by the lacteals to the fat depots, without passing through the liver, according to the views of Frazer and his colleagues. It is not likely that medicinal paraffin emulsions contain globules small enough to be absorbed, and they may therefore continue to be regarded as simple intestinal lubricants, apart from the fact that we have no reason to believe that deposition of small quantities of paraffin in the fat depots is in any way positively harmful. However, the ingestion of liquid paraffin frequently or in large quantities may have an adverse effect on the body's vitamin-A status, for much of our vitamin A is available to us from the conversion of carotene in vegetable foods, and the absorption of carotene is seriously reduced by the presence of excessive hydrocarbon in the alimentary tract.

### Dercum's Disease

Q.—Can the diagnosis of Dercum's disease be made clinically and is there any specific hormone treatment for it?

A.—Before making the diagnosis of Dercum's adiposis dolorosa in an indefinite case it is advisable to remove one of the lumps for microscopical examination. The symmetrical deposition of fat, and its painful character, may be met with in

varying degrees in all types of adiposity. There is no specific hormone therapy, but the usual treatment for adiposity—diet, diuretics, and moderate doses of thyroid—may be helpful.

### Classification of War Wounds

Q.—What, if any, work has been done on the classification of military casualties during the recent war? I should like to know whether there is any classification of wounds along the lines of the length of time a patient is militarily unfit; also whether any surveys have been made in order to classify wounds statistically in "weapon groups"—that is, wounds caused by shell-fire, mortar-fire, high-velocity bullets, mines, etc. Is there any well-established criterion of wound severity based on the transfer of energy, or rate of transfer of energy, from a missile to the human body?

A.—A certain amount of work has been done by the statistical branch of the Army Medical Department along the lines indicated in this question—that is, classification of wounds according to the length of time a patient is militarily unfit. These figures, which are based on the results following the first two months after the Normandy invasion, are to be found chiefly in the War Office *Monthly Bulletin of Health Statistics*, 9th and 11th issues (July and September, 1945). Regarding the second part of the question—the classification of wounds into "weapon groups" and the relation of the transfer of energy from a missile to its effect on the human body—this has been dealt with at some length in an interim report of the Military Operational Research Unit (August, 1946), to which is attached a good bibliography on this and related subjects.

### Toxicity of Moth-balls

Q.—Recently I saw an infant who had eaten about one-quarter of a moth-ball, apparently without ill effect. What are the possible toxic effects of moth-balls and what is the treatment?

A.—Moth-balls are nowadays made of naphthalene, though they used to be of camphor. Naphthalene has a very low toxicity because little is absorbed, but huge doses may produce parenchymatous nephritis. In doses of 3–12 gr. (0.2–0.8 g.) naphthalene is used as an intestinal disinfectant and vermifuge. The *Extra Pharmacopoeia* says that 2 g. over the course of two days has proved fatal to a 6-year-old child, and suggests as treatment that the stomach should be emptied by an emetic or stomach-tube; that a purgative dose of magnesium sulphate and demulcent drinks should then be given, but no oils or fats.

### NOTES AND COMMENTS

Reflections of a Haemophilic.—Mr. WILLIAM CAMP (Long Ditton, Surrey) writes: I am a haemophilic of 52 years of age. . . . During the period from my birth until I was over 30 years of age I had spent over 20 years in hospital. I had almost no schooling and my education was very little, so please forgive me if my writing becomes confused. Apart from this awful haemophilia I don't know what it's like to feel "off colour". . . . Over 50 years ago my brother bled to death through circumcision. . . . When I was born my mother was a widow and I was brought up in the world's worst slum tenements, in Islington. My mother was ignorant about the complaint. I spent my early childhood in the tiny slum courtyard with hundreds of other kiddies. I can just remember being booted around and being bashed about. My playthings, I recall, were pieces of broken coloured glass and rusty tin cans. Lumme! I must have spent the first 16 years of my life in hospitals. I can just remember when I was about 10 years old I had a tooth drawn. I remember blood, blood, blood, day and night, night and day, until I was picked up somewhere and taken to hospital. At 16 I was ready to face the world alone—ignorant, and badly crippled in my legs through continuous painful swellings in my knees. I can remember seeing my mother once before I took on the whole world alone. I can just remember her clasping my cut thumb and plastering on to the cut a thick dirty old cobweb which she had pulled from the corner of her "sitting-room." (The sitting-room was also the dining-room and bedroom and, I believe, the lavatory for four of us.) My mother told me that I was a "bleeder." I didn't quite know what that meant, but I believe that I thought that it was my religion. I soon found out! One of my first jobs was in a glass-making factory. At dinner-time we used to stop in the workshop and the men used to throw old sacks and their coats on to piles of splintered glass. I can't remember any of them ever being cut. Neither was I. . . . Once I worked in the kitchen of a large

institution. Speed was the motto. The chef took a liking to me and one day he said that he would make me "the fastest man in the country at chopping up runner beans." The secret was to have a carving knife with an edge like a razor, and to slice the bean close up to the fingers. That time I "bandaged" my cut thumb with a good blob of dough about as big as a hen's egg. I changed the "dressing" every 2 hours for about a week. I kept the blood-sodden dough out of sight as much as I could because I was shy of telling people that I was a "bleeder." . . . I am very poor, yet I should bet that no living soul in this wide world has been shown greater kindness and sympathy than I have received from doctors and nurses. If the nurses have been angels to me (and they have, indeed), my doctors have had a very large dose of the "divine" about them. More than half a dozen doctors have pulled me back from the grave. Why? I've been a bloody nuisance to them most of my life. . . . Why do they do it? It's splendid! It's magnificent! It's superb! It's a miracle! It's—being a doctor. It's the quality of God in man. . . .

I can remember now how, about 30 years ago, I had been bleeding for about 10 days. Doctor said, I believe, "If it doesn't stop soon I shall have to cut one of your veins and let your blood mingle with his"—he said that to the sister, a sweet, lovely girl. She said to him, "Cut where you like. Start now!" That horrified me. I thought that I'd rather do anything than see her be maimed for me. I couldn't think what to do. So I stopped bleeding. . . . I remember how, after bleeding in my tongue for 12 days and nights, I walked and walked all night through with my tongue hanging right out—12 hours a night for 12 nights in the freezing air. The ambulance took me to hospital. I remember the shock when the doctor told me that he had given me snake poison.

I remember how a beautiful, wonderful woman fell in love with me about 20 years ago. I told her everything I knew about my haemophilia. She said, "Right, we get married to-morrow." That was the biggest shock of all. She still loves me. . . .

A long time ago I read an article in some English health journal dealing with "selective breeding" in human beings. . . . They advocated the sterilization (or asphyxiation) of the unfit. Haemophiliacs were about the first on the list to be sterilized. I am not sure about this, but I believe that 20 years ago if I knew as much as I now know I would have asked for sterilization.

I have a son 18 years of age. He is 6 feet tall and is classified A1 in the Army. . . . Through hard study and a brilliant intellect he has put himself on the road to becoming one of the finest mathematicians in the country one day. . . . Lucky that I had a son? Shouldn't he have been born? I have another son of 13 years. He has only had measles. I have a third son aged 7. So to the eugenists I would say, "So what?" Lucky to have 3 boys? I don't feel clever over the fact that my children are boys. I'm not clever. Are the eugenists so very hot? . . . I've got through so far—thanks mainly to my wife and to your wonderful profession.

**Pink Disease.**—Dr. A. E. BERNSTIEN (Liverpool) writes: It was of interest that I read the reply by Dr. G. M. B. Hales (Nov. 29, 1946) to a correspondent who asked advice about a case of pink disease. He mentioned that he has treated these cases with intramuscular injections of liver extract and vitamin B twice weekly. I have just had a case of a baby of 10½ months which at three months of age started with diagnosed pink disease and gradually lost weight all the time since then. When the child came to me it had all the signs of pink disease and was in a very sorry state. I treated the case with liver extract and vitamin B in a similar manner to that which Dr. Hales describes, with the exception that I added hydrochloric acid by mouth and calcium by injection. The results were surprisingly good. The child started to gain weight from the first three or four injections, and there was a complete loss of irritability. I found that I could finish with the child after about fourteen injections.

**Food Allergy.**—The adviser responsible for the answer to a question about food allergy which was recently criticized by Dr. John Freeman (Nov. 29, p. 896) writes: Dr. Freeman's contributions . . . in the past to our knowledge of hay-fever are so outstanding that his present statements on food allergy may be taken by your readers to be a reflection of present-day views on the management of an allergic patient. This, however, is unfortunately not true. The statements, "The way to test is by a skin test with egg protein; this is quite reliable for finding a positive or negative test to that particular sensitivity . . ." and "trial dieting is very fallacious . . ." are quite contrary to modern views as expressed in standard books on allergy, for example, *Allergy in Theory and Practice* by R. A. Cooke; *Clinical Allergy* by A. H. Rowe; *Allergy in Practice* by S. M. Feinberg; *Clinical Allergy* by L. Tuft; *Allergy in Practice* by W. T. Vaughan; others could be mentioned, as well as innumerable articles on the same subject. In fact it is the undue reliance on the results of skin tests which has brought discredit on much of the work done on allergy in the past. All these books

agree that it is only by careful trial dieting that food sensitivities can be found and proved beyond all doubt. May I quote from the preface of Rowe's book?—"The frequency of the negative skin reaction in food allergy and the fact that positive tests are only important when checked by clinical trial have become assured. . . ." Finally, everyone will not agree with Dr. Freeman's statement, "The child can be desensitized with egg protein." Chobot, in the chapter on food allergy in *Allergy in Theory and Practice*, by R. A. Cooke, writes, "Treatment by desensitization, so-called . . . is uncalled for and ineffective . . ." and "oral therapy with drop-by-drop increases has never been proven to produce the tolerance attributed to it but which nature unaided will provide in practically 90 to 95% of the cases." These are views with which the writer at least is in profound agreement.

**Prophylaxis of Dental Caries.**—Mr. R. B. D. STOCKER, L.D.S. (London, N.W.), writes: Your answer to a correspondent on this subject (Nov. 29, p. 895), while disposing of the suggestion that vitamin-D therapy might be useful, gives no positive advice at all. It is true that no single preventive measure except local fluoride application or any combination of preventive measures has yet been proved to be effective by rigorously controlled human experiments. Nevertheless there is ample experimental and other evidence to justify treatment which can confidently be expected to lessen caries in young adolescents. Local applications to the teeth of sodium-fluoride solutions are effective in children, but there is little evidence that such treatment is valuable after about the age of 15. The patient's consumption of refined sugar should be reduced and the calories lost should be replaced in detergent foods such as raw fruit and vegetables, preferably taken at the end of meals. This is effective in all but a small proportion of specially susceptible cases. A rational tooth-brushing technique must be taught and not merely demonstrated, and must be used after meals if possible; when this is impossible, rinsing should be substituted. Dental treatment should also include thorough polishing of the teeth several times a year. Painting with silver nitrate to disclose and arrest incipient caries before cavitation has begun may be classed as preventive or as curative treatment.

It is unfortunate that your correspondent cannot simply be told to refer his patients to a dental surgeon, but preventive dentistry will not develop until the public and the medical profession demand it, and it must somehow be made more profitable to the dentist than surgical and mechanical dentistry. Let us hope that the bureaucratic methods of the school dental service with its "output" of fillings and extractions (in the ratio of 100:180) do not foreshadow those of the brave new Health Service. The proposed introduction of hygienists suggests, rather, that the more preventive outlook of our American colleagues and the R.A.F. dental branch will be adopted.

**Judicial Hanging.**—Dr. J. R. V. FOXTON (New Norfolk, Tasmania) writes: I was interested in the answer to the question on the above subject (July 26, p. 160) and in the comments of Col. Rutherford (Aug. 16, p. 282). When a student at the Melbourne University, I attended a lecture on judicial hanging given by Prof. Frederic Wood Jones to a combined meeting of the Medical Students' Society and the Law Students' Society. If my memory serves me correctly he stated that the placing of the knot at the angle of the jaw (as is, I believe, the custom in British countries) rarely, if ever, fractures or dislocates the vertebral column, and death in judicial hanging occurs from strangulation or from fracture of the base of the skull. In either case consciousness may be retained for some time and death occurs slowly and painfully. He further stated that invariable fracture or dislocation of the cervical spine could only be obtained (a) by employing a very long drop, approximately that required to produce decapitation, or (b) by the placing of the knot under the chin, in which position it must be retained by some mechanical appliance. It would appear that judicial hanging as practised is an unnecessarily cruel and barbarous form of execution, and that reform is long overdue.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 13 1947

## GENERAL MEDICAL COUNCIL

(Continued from p. 132)

### Convictions

On Nov. 27 the Council considered the case of James Albert Seavers, registered as of Benedon Road, Sheldon, Birmingham, who was summoned on the charge that on Aug. 13 last he had been convicted at the Birmingham magistrates' court after having pleaded guilty of an indecent assault upon a girl aged 14, and had been fined £50 or three months' imprisonment.

Dr. Seavers attended, accompanied by Mr. Basil Harwood, counsel, instructed by Brasseur and Oakley, solicitors, on behalf of the Medical Protection Society. An application by respondent's counsel to have the case heard *in camera* was refused.

Mr. Winterbotham, the Council's solicitor, said that since the end of 1946 Dr. Seavers had had among his patients the family of which the girl in the case was a member. He had been treating the girl for sore throat, and on July 8 he called at the house, said he wanted to examine the girl, and while the mother was dismissed from the bedroom on some errand he committed the assault. Later he said to the police that he had lost control of himself, that "something snapped," and at the police court it was stated that he was a sick man and that there was a psychological element in the case. He had had a breakdown while going to and serving in West Africa in the R.A.M.C., and had sought relief in drink.

Dr. A. S. Thorley, a psychiatrist on the staff of the Sutton Emergency Hospital, said that Dr. Seavers had been under his care since Oct. 6. He had an anxiety condition associated with chronic alcoholism. There was a family history of mental disorder. He had had three previous anxiety attacks, the first while taking his second M.B., and the second in West Africa, where he suffered from malignant tertian malaria. On returning he was posted to a busy depot in Yorkshire and had a severe breakdown. He had been six months under treatment at Crichton Royal and his condition improved. Dr. Thorley expressed the view that he had the chance of making a good recovery. He understood that employment as a ship surgeon on a cargo line was open to him, and he thought that this would be suitable. Mr. Harwood recounted the respondent's unfortunate history, and read a testimonial from a medical colleague.

The Council, after private deliberation, found the conviction proved and directed the Registrar to erase Dr. Seavers's name from the *Medical Register*.

The Council considered the case of Hugh Boyd Gillespie, registered as of Blairhall Avenue, Langside, Glasgow, who was summoned on the charge that on March 4, 1947, at the Sheriff Court, Glasgow, he had been convicted of being under the influence of drink to such an extent as to be incapable of having proper control of the car of which he was in charge, and had been fined £30 or three months' imprisonment and disqualified from holding a driving licence for two years. Dr. Gillespie attended, accompanied by Mr. Oswald Hempson, solicitor.

Mr. Winterbotham read the police report of the offence, which resulted in a collision between the car and a tramcar, no one, however, being injured. Dr. Gillespie had appeared before the Council previously, in 1942, to answer to a conviction for a similar offence in that year and a previous one in 1940, but after postponing judgment the Council on that occasion did not see fit to erase his name.

Mr. Hempson urged Dr. Gillespie's health as an extenuating circumstance, and put in a certificate from a psychiatrist at the Southern General Hospital, Glasgow, to the effect that Dr. Gillespie had been treated by him as a voluntary patient in the mental observation wards in the early part of this year. He found him to be suffering from chronic exhaustion, the result of long-standing personal maladjustment, aggravated by overwork in general practice.

He had responded satisfactorily to treatment. During Dr. Gillespie's stay in hospital he had shown an exaggerated and atypical response to the drugs used in treatment, which justified the inference that he might show a similar response to a small quantity of alcohol, which was all that was concerned in the offence leading to the present conviction. Mr. Hempson put in some testimonials, including one from Dr. Stuart Laidlaw, M.O.H., Glasgow, as to Dr. Gillespie's satisfactory conduct while in the service of the corporation, and an unsolicited testimonial from a patient. He gave an assurance that Dr. Gillespie would never again touch spirits, which he thought a more valuable assurance than a general one of abstinence from alcohol.

The Council found the conviction proved, and took a grave view of the fact that he had not yet overcome a habit discreditable to himself and potentially dangerous to his patients. But it took into account the illness from which he had recently suffered and postponed judgment for two years, requiring him to come forward at the end of one year with testimonials as to his conduct in the meantime.

The Council next considered the case of Ralph Martin Case, registered as of Gillott Road, Edgbaston, Birmingham, who was summoned on the charge that in May last, at Marylebone, he had been convicted of being unlawfully in possession, when not authorized, of 25 1/4-gr. tablets of morphine and 100 1/4-gr. tablets of heroin, contrary to the provisions of the Dangerous Drugs Act, 1920, and in August last, again at Marylebone, of attempting without lawful authority to procure five tablets of diamorphine, contrary to the provision of the same Act as amended by the Dangerous Drugs and Poisons (Amendment) Act, 1923. On the first conviction he had been fined 40s. and 2 guineas costs, and on the second conviction fined £25 or three months' imprisonment.

Mr. Winterbotham said that it was not for the practice of his profession that Dr. Case had used the drugs, but entirely for himself. He gave particulars of the events which led up to the convictions.

Mr. Gerald Howard, on behalf of the respondent, said that the case disclosed a miserable story, but, unlike many cases of the kind, the doctor had involved only himself in disaster. Dr. Case qualified at Birmingham in 1934 with an honours degree. In 1930 he gained the Queen's prize for the best student of the year at his university and in 1934 the Sampson Gamgee memorial prize for surgery. He desired to be a surgeon, but in order to maintain his wife, whom he married in 1937, he went into a general-practitioner partnership at Newbury, which, being a reception area during the war, involved him in a great deal of work and strain, especially as one of his principals was away on service. In 1940 he began taking morphine, believing that he could keep free from addiction, but in the year following he found himself addicted and twice put himself under the care of Dr. Laughton Scott at Tunbridge Wells and also signed an undertaking to the Home Office. In 1943, while in the R.A.F., he again became addicted, called at the Home Office and informed them of his condition, and again went for treatment. In 1944 he became free for some time, but in 1945 his wife, who was an American, decided to go back to America and take their two children with her. On a relapse in 1946 he wrote to certain firms of chemists asking them on no account to supply him with any more drugs; he also begged the police to take away his licence, but he was informed that this was not possible without court proceedings. Such proceedings were taken in May, and constituted the matter referred to in the first conviction. The magistrate had been reluctant to impose any penalty until it was pointed out to him that unless he did so there were difficulties in taking away the doctor's licence and the doctor himself wished that course to be taken. He undertook treatment at Maudsley Hospital, from which he was discharged cured at the end of May, and had taken no drugs since.

Owing, however, to unfortunate domestic and financial circumstances, partly arising from a misapprehension, and feeling that he had absolutely no future, he made an attempt to procure certain drugs from a chemist, but was arrested before he could do so. His circumstances, domestic and financial, had now entirely altered

for the better, and, moreover, he had obtained employment in the Medical Statistics Branch of Birmingham University. Prof. Lancelot Hogben, in whose department Dr. Case was now working, wrote that Dr. Case was a man of exceptional gifts and high character and endowed with an aptitude for research. He was unfitted for the wear and tear of general practice by a highly strung temperament, but should find his proper niche in a university post. He was now an active and invaluable member of a team, and Prof. Hogben added that he spoke with the full sympathy of several of his professional colleagues of the medical school when he expressed the hope that a happy environment among congenial colleagues would elicit the full manifestation of the undoubted gifts which Dr. Case possessed. In his department he had an opportunity of social usefulness for the advancement of medicine of a kind which did not bring him into contact with the individual patient.

Dr. Case went into the witness box and declared that his addiction had been solely caused by overwork and had been mainly an addiction to morphine and not cocaine, and that he had now freed himself from such addiction.

The Council, after deliberation *in camera*, found the convictions proved, but the President said that the Council was anxious to give the doctor a full opportunity to establish his recovery and therefore had postponed judgment for two years, until the November session, 1949, but would require him in November, 1948: to appear and produce testimonials.

The Council considered the case of John Hollis Drummond Lawrie, registered as of the Town Hall, Macclesfield, and found that a conviction against him had been proved, but decided not to instruct the Registrar to erase his name from the *Medical Register*. The Council took a similar course in the case of Allan Gillies Foreman, registered as of Lussielaw Road, Edinburgh, finding a conviction proved, but deciding not to instruct that his name be erased.

The Council, on evidence of the illness of the practitioners, postponed until the next session the hearing of four cases.

#### Restorations

The following names were restored to the *Medical Register* after previous penal erasure: Arthur Carr, Isaac David Klein, Gerald Green, Louis Aimee Newton, Horatio Matthews, Thomas Sylvester O'Neill, William Vincent Saint John Sutton, John Mackay Young.

The Council, *in camera*, considered a report of the Executive Committee on the question whether the Medical Acts empower the Council to make provision for the removal from the *Register* of the names of practitioners at their own request; and, if so, whether it is expedient that such provision should be made. The Council did make such provision from 1887 to 1937, but in 1937 it rescinded the relevant standing orders on the light of legal advice that they were *ultra vires*.

Prof. W. W. D. Thomson was nominated by the Council for appointment by the Minister of Home Affairs for Northern Ireland as a member of a tribunal constituted under the Dangerous Drugs Regulations, 1938 (Northern Ireland).

Formal business was transacted, and the session closed on Nov. 28.

## HEARD AT HEADQUARTERS

#### More Vice-chairmanships

We record here some other instances of the election of medical men, the choice of the local profession, to the vice-chairmanships of Executive Councils. Dr. N. E. Waterfield, a member of the B.M.A. Council and chairman of the Ethical Committee, has been made vice-chairman of the Surrey Executive Council. Dr. Alex S. Wilson, secretary of the Holland Division in Lincolnshire, has been elected vice-chairman of the Holland Executive Council. Dr. John McCrea, an ex-chairman of the Reading Division, is vice-chairman of the Executive Council for Berkshire. Dr. Robert Ellis, after 25 years as chairman of the Local Medical and Panel Committee for Cambridgeshire and a like period as vice-chairman of the Insurance Committee, becomes vice-chairman of the Executive Council for his county. Dr. J. Kerr, chairman of the Cheshire Local Medical and Panel Committee, has been made vice-chairman of the

Executive Council for the County Palatine. Dr. N. J. Cochran, chairman of the Burton-on-Trent and District Advisory Committee on Industrial Health, is vice-chairman of the Executive Council for Burton. There may be many other examples. The co-option of medical representatives on county and county borough health committees, notwithstanding the expressed wish of the Minister of Health, seems to differ considerably in different parts of the country. Thus in the north-west, in Cheshire, two such representatives have been appointed, but in the east, in Holland, the county council has taken no action.

#### Two Special Committees

Two of the special committees recently appointed by the Council are getting down to their work. The committee on the nursing problem held its first meeting a week or so ago, and appointed as its chairman Dr. Mary Esslemont, of Aberdeen. Its 24 members include representatives from the British Hospitals Association, The Royal College of Nursing, and the King Edward's Hospital Fund, as well as the chairmen of the principal standing committees, and ten other B.M.A. representatives, six of them members of the Council. Its first business was the consideration of the Working Party report, on which the Association has been asked to submit a written statement to the Minister. The Committee on Nutrition has also started its work. The first document laid before it was the report of the earlier committee, prepared under the late Sir Kaye Le Fleming's chairmanship in 1933. The tables of individual diets given in that report strike a rather poignant note at the present time. For example, the suggested weekly adult ration adequate to support health and working capacity includes 1 lb. beef, 1/2 lb. minced meat, 1/2 lb. bacon, 1/2 lb. corned beef, 1/4 lb. ox liver, 2 eggs, 1 1/2 pints of milk, 1/4 lb. butter, and some seventeen other items, and the cost of the first-class proteins in this diet was less than half a crown. Here is a target for Mr. Strachey.

## Correspondence

#### National Health Service

SIR,—In most of the recent correspondence under the above heading the accent has been very much on what the doctors think of the proposed Service. Surely the thoughts of their patients are of even greater importance, and after questioning many of mine during the last few months I am left in no doubt that the great majority of them consider that a completely State-controlled service, with its dangling earrot of regular hours, week-ends off, and night calls twice a week, is a menace to the doctor-patient relationship built up by past generations of medical practitioners.

All of us presumably know what we are in for when we take up general practice—a hard life with compensations which make it worth while, one of which surely is the gratitude of patients who know that they have our undivided loyalty. To share that loyalty between patient, State, and possibly other doctors at a health centre will undermine our profession and lower the standard of service which the public have rightly come to expect.—I am, etc.,

Lewes, Sussex.

J. P. MATTHEWS

#### Unity Through the Majority

SIR,—With reference to your latest appeal for unity (*Journal* Nov. 15, p. 777), you must be aware that much of the distrust is not due to differences in politics but to distrust of each other among the various members of the profession, due partly, I believe, to the failure of the Protection of Practitioners Scheme during the war, the failure being due entirely to the lack of co-operation within the profession. Speaking for myself, if asked whether I would work in the State Service, I would only be prepared to refuse if I could be reasonably sure that at least 90% of the profession would support the refusal. I suggest therefore that in addition to the

question as to whether or not the proposal should be accepted another question is asked—namely, "Do you agree to accept a majority decision?"

It would surely be a great boost to our cause if instead of just announcing, say, that 60% are against accepting and 40% are for it we could state that 90% were willing to accept the majority verdict of the profession. And if the answer to the second question showed that we are not willing to accept a majority verdict, then we may as well stop talking about lack of democracy and give in to our would-be dictators.—I am, etc.,  
Newport Pagnell, Bucks.

A. A. CLAY.

### In the Vernacular

SIR,—I am heartily fed up with opening the *B.M.J.* and finding many pages filled with articles upon State medicine. When I came out of the Army and attended a local B.M.A. meeting upon this matter during its early stages, I asked to be informed of the general feeling of the doctors regarding the subject, and I was informed that 90% were against a State service. I privately suspect that the doctors are against it in general because of their own reactions to the monetary and dictatorial sides as they will affect them, which is not unnatural.

We are kept in the dark as to what is going on, and my own feeling is that a hard-headed determined man who wishes to fulfil his own ideals is just "putting us where he wants us." And now the date of the meeting has been altered and we trail along like good little choirboys! Why the dickens don't we have the guts to say, "Yes, some of the ideas are good, but we'll have the State Service the way we think is to the advantage of the public and the doctors. We shall not permit ourselves to be dictated to by you or anybody else!"

I expect that more flowery language will need to be used, although I believe that to call a spade a spade would show more stamina. I also expect that it will not be considered *diplomatique* to publish this letter, but I have "got it off my chest" and perhaps off those of some other colleagues. I like freedom; why give it up for the Minister of Health?—I am, etc.,

Chilston, Lincs.

A. F. CHALKLEY.

### Records of Insured Patients

SIR,—One of my panel patients after many illnesses has now ceased to be insured. According to the rules I have had to return her envelope containing the whole history of her case. She still remains my patient, but I have now no record whatever to which to refer in case of subsequent illness. I wonder that this point has never been ventilated before. Where do all these records go, and who ever refers to them? Surely in such cases we should be allowed to retain these valuable aids to our future treatment.—I am, etc.,

Cambridge.

A. E. MOORE.

### Car Priority

SIR,—It is to be hoped that the resolution of the Annual Panel Conference reported in the *Supplement* of Nov. 8 (p. 109) pleading for effective priority for doctors in the supply of motor-cars be most rigorously pursued. Surely the combined resources of the manufacturers could deal effectively and speedily with the 2,000-3,000 cases of urgency in our profession, even though the supply of cars for the home market is limited.

It is a deplorable state of affairs when the B.M.A. must state that "technically in the list of priorities doctors, nurses, and midwives were second only to the police, but this did not work out in practice." What is the good of priority schemes if these are not carried out in practice? The medical profession as a whole should protest vigorously against this reprehensible state of affairs.—I am, etc.,

Leeds.

I. ROSE.

### "Doctor" Sign on Cars

SIR,—In view of the fact that after Nov. 30 all users of cars will be under police observation and must furnish evidence, when called upon, that they are using their car for some specific purpose approved of by the Ministry of Fuel, it is more than probable that doctors will be called upon frequently to state

why their car was at a certain place at a certain time—perhaps several days previously—or that they will be stopped and questioned while out on their rounds. I for one do not wish to drive round again with a "doctor" label on my windscreen and, with due deference and diffidence, offer a solution which I hope will be considered by the B.M.A.

My suggestion is a small badge about 3 in. square which can be stuck on the wind-screen in the top left-hand corner: the badge a red caduceus on a white background, with the words, "Issued by the B.M.A. (or Local Panel and Medical Committee)" and "approved by the ——— Borough/County Police," or something to that effect to make it officially recognized by the police. I am quite sure this would save both the police and doctors a lot of unnecessary trouble.—I am, etc.,

Northampton.

J. P. TRAYLEN.

## H.M. Forces Appointments

### ROYAL NAVY

#### ROYAL NAVAL VOLUNTEER RESERVE

Temporary Surgeon Lieutenant R. A. McKeown has been transferred to List I of the permanent R.N.V.R.

### ARMY

Colonel E. Percival, D.S.O., M.C., late R.A.M.C., has retired on retired pay.

#### ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel T. L. Henderson, having attained the age for retirement, is retained on the Active List supernumerary.

Major I. N. Fulton has retired, receiving a gratuity.

Captain H. G. Skinner to be Major.

*Short Service Commission*.—B. McConkey to be Lieutenant.

#### REGULAR ARMY RESERVE OF OFFICERS

Major-General D. S. Skelton, C.B., D.S.O., late R.A.M.C., having exceeded the age limit for liability to recall, has ceased to belong to the Reserve of Officers.

#### ROYAL ARMY MEDICAL CORPS

War Substantive Major S. P. Bellmaine has retired and has been granted the honorary rank of Lieutenant-Colonel.

#### TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel J. W. Craven, M.C., T.D., has relinquished his commission.

#### LAND FORCES: EMERGENCY COMMISSIONS

##### ROYAL ARMY MEDICAL CORPS

War Substantive Captains G. R. Wadsworth, H. A. Friedlander, and A. L. M. Christie have relinquished their commissions and have been granted the honorary rank of Major.

War Substantive Captain R. F. Griffith-Evans has relinquished his commission on account of disability and has been granted the honorary rank of Captain.

*Short Service Commission, Specialist*.—War Substantive Captain T. W. Howat has relinquished his commission and has been granted the honorary rank of Major.

### WOMEN'S FORCES

#### EMPLOYED WITH THE R.A.M.C.

War Substantive Captain D. J. B. Falconer has relinquished her commission and has been granted the honorary rank of Major.

War Substantive Captain H. M. Teunon has relinquished her commission and has been granted the honorary rank of Captain.

#### ROYAL AIR FORCE

To be Flight-Lieutenants: J. A. MacCarthy, O.B.E., T. H. Redfern, F. Latham, and A. J. K. Gallagher.

Flight-Lieutenants R. D. Bruce, A. L. Knipe, M. N. Phillips, and W. D. Peock to be Squadron-Leaders (Substantive).

To be Flying Officers: P. D. Sutton, M. D. Warren, T. C. Gibson, A. Stewart, and J. L. Struan-Marshall.

#### ROYAL AIR FORCE VOLUNTEER RESERVE

War Substantive Flight-Lieutenant J. Millar has resigned his commission, retaining his rank.

Flight-Lieutenants (Substantive) M. J. Cahalane and C. E. Tait have relinquished the temporary rank of Squadron-Leader.

Flying Officers P. W. Dagger, R. A. Armstrong, N. L. Bailey, J. Buchanan, W. K. Christopher, J. G. R. Ellis, R. E. Glenn, H. B. W. Greig, W. A. Jackson, W. R. Johnson, L. F. Levy, D. O. Lewis, J. W. Little, G. H. Lloyd, R. J. McWilliams, T. C. Nicol,

R. W. Rapinot, D. F. Robertson, R. H. Sage, J. A. Sindell, D. C. Adamson, N. Coulshed, A. C. Edwards, D. A. W. Edwards, A. W. Gilks, E. J. Innes, R. F. M. Jones, H. A. K. Rowland, A. D. Verniquet, I. G. Waugh, J. A. Waycott, R. H. Whitworth, C. P. Williamson, G. R. Wotton, R. Youngman, C. R. Kirkpatrick, K. W. Robinson, W. E. Arnold, C. E. Bagg, R. W. Baxter, J. H. Burt, F. E. V. Cant, R. B. Carr, S. Davis, E. Dillstone, J. C. Ham, A. C. Hill, R. A. Houston, W. M. Ironside, S. J. Krister, S. Lewis, D. W. J. O'Neill, C. Ounsted, J. H. Ridgwick, R. C. Robb, G. F. Roberts, R. A. K. Ross, C. S. Shaw, J. L. G. Thomson, W. F. Toomey, L. V. Martin, E. V. de C. McDill, J. D. Nelson, J. P. Nowlan, K. I. Roberts, L. Silverstone, T. A. Wylie, P. O. Yates, N. J. Blockey, N. K. Connolly, E. J. D. Craig, W. T. Edwards, R. H. Ellis, D. E. Fletcher, G. Gomez, J. H. Gough, A. S. Grimble, C. T. Hough, R. C. Jennings, N. D. Kapur, P. R. McElwain, D. Mackinnon, J. B. Metcalfe, H. R. Morton, E. G. Murphy, T. M. Nott-Bower, T. H. Park, J. A. Rycroft, S. A. K. Stokes, E. Tobin, J. M. Ward, and H. Wainstead to be War Substantive Flight-Lieutenants.

Flying Officer L. M. Henry has resigned his commission.  
Flying Officer J. Cunningham has relinquished his commission on account of medical unfitness for Air Force service.

### WOMEN'S FORCES

EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

Flying Officer M. E. Buckley to be Flight-Lieutenant (Substantive).

### COLONIAL MEDICAL SERVICE

The following appointments have been announced: I. M. Almond, M.B., Ch.B., Lady Medical Officer, Malaya; E. N. Emmerson, M.R.C.S., L.R.C.P., and J. A. Ward, M.R.C.S., L.R.C.P., Medical Officers, Tanganyika; H. B. Gibson, M.B., B.S., Medical Officer, Nigeria; H. P. Fernandes, M.R.C.S., L.R.C.P., Health Officer, Tuberculosis, British Guiana; A. W. Sampey, M.R.C.S., L.R.C.P., Medical Officer, Kenya; B. N. V. Wase-Bailey, M.D., Senior Medical Officer (Health), Sierra Leone; L. M. Ram, M.B., B.S., Medical Officer, Malaya.

### B.M.A. LIBRARY

The following books have been added to the Library:

- Anderson, C. G.: *An Introduction to Bacteriological Chemistry*. Second edition. 1946.  
Ascoli, M.: *Nuove Vedute sulla Malaria*. 1947.  
Atkins, H. J. B.: *After-treatment*. Third edition. 1946.  
Becker, S. W., and Obermayer, M. E.: *Modern Dermatology and Syphilology*. Second edition. 1947.  
Brinn, W. R.: *Diseases of the Nervous System*. Third edition. 1947.  
Bréhan, J.: *Le Chirurgien en Présence de l'Etat Diabétique*. 1946.  
Cibert, J.: *La Tuberculose Rénale sous l'Angle de la Thérapeutique*. 1946.  
Cox, L. B., and Tolhurst, J. C.: *Human Torulosis*. 1946.  
Damianovich, J., and Freyre, A. V.: *La Apendicitis en la Primera Infancia*. 1945.  
Danielopolu, D.: *La Digitale et les Strophantines*. 1946.  
Davidoff, L. M., and Dyke, C. G.: *The Normal Encephalogram*. Second edition. 1946.  
Delarue, J.: *Le Problème Biologique du Cancer*. 1947.  
Dickinson, F., and Hall, K. G. C.: *An Introduction to the Prescribing and Fitting of Contact Lenses*. 1946.  
Goldring, W., et al.: *Experimental Hypertension*. 1946.  
Greenstein, J. P.: *Biochemistry of Cancer*. 1947.  
Hanmen, R.: *Studies on Impaired Fertility in Man*. 1944.  
Horney, K.: *Our Inner Conflicts: a Construction Theory of Neurosis*. 1946.  
Kamath, M. A.: *Ophthalmic Surgery and Sight Testing*. 1944.  
de Kok, W.: *First Baby*. 1946.  
Lufsig, W.: *Natural Treatment of Eye Diseases*. 1947.  
Merlino, A.: *Il Distacco Intempestivo di Placenta Normalmente Inserta*. 1943.  
Moncrieff, A., and Thomson, W. A. R. (Editors): *Modern Diagnosis (Practitioner Handbook)*. Second edition. 1946.  
Nicaud, P.: *La Periartrite Nouvelle: Maladie de Kussmaul*. 1946.  
Nielsen, J. M.: *A Textbook of Clinical Neurology*. Second edition. 1946.  
Ranson, S. W.: *Anatomy of the Nervous System*. Eighth edition, revised by S. L. Clark. 1947.  
Raper, H. R.: *Man Against Pain: the Epic of Anaesthesia*. 1947.  
Rice, J. V.: *One Hundred Years of Gynaecology, 1800-1900*. 1945.  
Roxburgh, A. C.: *Common Skin Diseases*. Eighth edition. 1947.  
Scott-Wilson, H. W.: *Aids to Bacteriology*. Seventh edition. 1946.  
Spillane, J. D.: *Nutritional Disorders of the Nervous System*. 1947.  
Spivack, J. L.: *Urgent Surgery, Vol. I*. 1946.  
Stopes, M. C.: *Contraception (Birth Control)*. Sixth edition. 1946.  
Strachan, G. I.: *Textbook of Obstetrics*. 1947.

## Association Notices

### SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: Ernest Hart Memorial Scholarship of the value of £200 per annum; a Walter Dixon Scholarship of the value of £200 per annum; a four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1, 1948. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the first award of the Insole Scholarship of the value of £250 for research into the cause and cure of venereal disease.

#### Conditions of Award: Applications

Applications for scholarships must be made not later than Friday, April 30, 1948, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

### Diry of Central Meetings

DECEMBER

17. Wed. Special Meeting of Council, 11 a.m.

### Branch and Division Meetings to be Held

**BATH, BRISTOL AND SOMERSET BRANCH.**—At Large Physics Lecture Theatre, The Royal Fort, Bristol University, Wednesday, Dec. 17, 8.30 p.m. Dr. Charles Hill: The Present Position. All medical practitioners in the area of the Branch are invited.

**GREENWICH AND DEPTFORD DIVISION.**—At Miller Hospital, Greenwich Road, S.E., Wednesday, Dec. 17, 9 p.m. Dr. Geoffrie Loxton: Modern Medical Treatment.

**NORTH OF ENGLAND BRANCH.**—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, Dec. 18, 7.15 p.m., Clinical Demonstration by Mr. G. A. Mason; 8.45 p.m. Address by Dr. Douglas Guthrie: The Patient—A Forgotten Factor in the Progress of Medicine.

### Meetings of Branches and Divisions

#### MORPETH DIVISION

A meeting of members of the Morpeth Division was held on Nov. 14. Those present were: Drs. Murray, Maclean, Stephenson, T. S. Brown, Hobbs, Macfarlane, Irvine, Skene, Macfie, Spitzer, and McGregor, of the Morpeth Division, and Drs. Lowry and McLaughlin, of the Blyth Division. In the absence of the chairman through illness the chair was taken by the vice-chairman, Dr. J. R. Murray.

Dr. Stephenson gave a report on the public relations conference held in Newcastle on Oct. 16. Following this, a discussion took place on the question of appointing a public relations secretary. Eventually it was proposed by Dr. Maclean and seconded by Dr. Stephenson that the decision should be postponed until the next meeting. Dr. Maclean then inquired if the secretary knew of the approach having been made by the Branch Council to the National Coal Board in connexion with the provision of insurance certificates to miners. The secretary stated that she had no information on the matter and it was agreed that she should get into touch with the secretary of the Branch Council and find out the position.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

- County Borough Councils.**—Barnsley, Gateshead.  
**Metropolitan Borough Councils.**—Fulham, Hackney, Poplar.  
**Non-County Borough Councils.**—Dartford, Leyton, Radcliffe.  
(limited to future appointments), Tottenham, Wallingford.  
**Urban District Councils.**—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Rohy, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.  
**Scottish Burghs.**—Motherwell and Wishaw.

LONDON SATURDAY DECEMBER 20 1947

## EXPERIMENTAL INVESTIGATIONS OF PARODONTAL DISEASE

### VI. FURTHER CLINICAL STUDIES OF SUGAR-CANE GNAWING IN TREATMENT OF GINGIVAL DISEASE

BY

J. D. KING, Ph.D., D.P.D., L.D.S.

Director, Dental Research Unit, Medical Research Council, King's College Hospital Medical School, London

Three previous reports have dealt with the aetiology, prevention, and cure of a form of parodontal disease in the laboratory ferret associated with dental calculus (King, 1944, 1945; King and Glover, 1945). The experimental findings clearly showed that, even in the presence of a nutritionally adequate diet, severe parodontal lesions occurred in this animal in the absence of supplements of short lengths of dietary bone plus muscular, tendinous, and periosteal attachments. Disease of the gum, and later of the periodontal membrane and alveolar bone, was in fact due to irritation and injury by deposits of tartar. Prevention of both calculus deposition and gingivitis, and eradication of these conditions when established, were effected by the friction provided by bone-gnawing, the importance of retaining muscular and other attachments being their inducement to gnawing of the bone by the ferrets. In other words, tartar deposition and parodontal disease were prevented or eliminated by adequate friction of the teeth and gingivae.

Some means was then sought of applying the animal data to the problem of parodontal disease in man. On the basis of unofficial reports that certain Jamaican natives were relatively free from gingivitis, it was considered that their habitual consumption of sugar-cane might be responsible—in short, that such apparently good gingival health might in fact be due to the same mechanical action (friction) operative in the prevention and cure of the ferret disease by bone. Supplies of sugar-cane were obtained and a preliminary investigation was made of the effect of cane-gnawing in the treatment of gingivitis in adults and institutional boys (King, 1947b), the main findings being summarized as follows:

1. The most striking results of the 7-8-week tests were the extremely rapid cessation of bleeding and soreness of the more severely diseased gingivae and the marked improvement in dental and interdental hygiene in all cases after daily gnawing of short lengths of longitudinally split sugar-cane.

2. The degree of resolution of the lesions was, however, largely dependent upon the extent to which the cane was able to remove dental calculus and to counteract any other sources of irritation. When calculus deposits were relatively slight and soft, recovery of gingival health could be achieved by sugar-cane therapy alone, but in the presence of heavy accretions of hard tartar resolution of the gum lesions was limited to cessation of bleeding and soreness (at least temporarily), defensive epithelial proliferation, and increased leucocytic activity.

3. The findings suggested that the beneficial effects of gnawing sugar-cane were associated with mechanical cleansing of the teeth and interdental spaces, removal of the soft tartar and superficial necrotic gum tissue, and stimulation of the natural defence reactions of the gingivae, due to friction of tooth and gum by the cane fibres and bark. At the same time increased

salivation and certain chemical or even antibacterial properties of the expressed sugar juice may have played a part in one or more of the recovery processes.

The present report mainly concerns the findings of a second clinical investigation on two further groups of boys from the same institution in which attempts were made to eliminate the tartar factor by dental scaling prior to cane therapy, and a comparison between the results of this and the previous study.

#### The Investigations

The examination methods and criteria were identical with those previously described, being confined to the incisor and canine regions of the denture (King, 1947b). In the second investigation, however, the teeth of both test and control groups were thoroughly scaled immediately before the experimental period of eight weeks began. In the latter study also, to avoid refrigeration, the Nigerian sugar-cane used was preserved by canning, which involved exhaustion of the cane-filled cans by steaming for 30 minutes, followed

Lower jaw.

Upper jaw.

Diagram of method of using sugar-cane. G, gum; T, tooth; B, bark of cane; F, fibrous core of cane. Pieces of cane 2-4 in. (5-10 cm.) long are slit longitudinally, thus enabling the teeth to bite into the fibrous pith of each half-piece. The direction of the biting stress, shown by the arrows, is approximately at right angles to the labial gum margin, and the frictional force reaches its maximum when the teeth and gingivae come into contact with the inner aspect of the sugar-cane bark. Each test subject received a piece of cane daily, one half for the upper and one half for the lower jaw.

by reheating of the sealed cans for a further two hours. The method of using the cane is illustrated by the accompanying diagram, and was identical in both investigations. The numbers of subjects in the various experimental and control groups are shown in the Table.

#### 1. Pre-experimental Data

It is first of interest to consider the clinical state of the subjects before the sugar-cane and other tests began. The condition of the lower anterior gingivae was similar in both investigations, but in the two groups of boys of the second study the average degree of gingivitis in the upper jaw

Table showing Effect of Gnawing Sugar-cane on Gingival Haemorrhage. 1st (Raw Cane, no Preliminary Scaling of Teeth) and 2nd (Canned Cane, with Preliminary Scaling) Investigations on Institutional Boys

	1st Investigation*			2nd Investigation†					
	Raw Sugar-cane (19 Boys) (No Controls)			Canned Sugar-cane + Scaling (11 Boys)			Controls + Scaling (12 Boys)		
	No. of Gum Regions Tested	Regions with Haem.		No. of Gum Regions Tested	Regions with Haem.		No. of Gum Regions Tested	Regions with Haem.	
Upper jaw:									
Before expt.	111	8	7.2	65	17	26.2	68	21	30.9
After expt.	111	2	1.8	65	7	10.8	68	18	26.5
Difference			5.4			15.4			4.4
Lower jaw:									
Before expt.	112	46	41.1	66	33	50.0	72	39	54.2
After expt.	112	8	7.1	66	6	9.1	72	31	43.1
Difference			34.0			40.9			11.1
Both jaws:									
Before expt.	223	54	24.2	131	50	38.2	140	60	42.9
After expt.	223	10	4.5	131	13	9.9	140	49	35.0
Difference			19.7			28.3			7.9

\* 1st investigation on boys of 15-16 years. † 2nd investigation on boys of 14-15 years.

was much greater. In other respects the oral conditions were comparable, the gingival lesions being of a severe non-ulcerative form associated with relatively heavy tartar deposits and/or grossly defective mouth hygiene.

#### Relative Incidence of Haemorrhage from Upper and Lower Gingivae

Comparison of the two investigations (see Table), made in the same institution but on different boys at different times of the same year, shows that the incidence of initial bleeding in the first study was 7.2% for the upper and 41.1% for the lower jaw. In the second investigation the respective percentages were 26.2 and 50.0 for one group and 30.9 and 54.2 for the other. There was, therefore, a considerable variation between the upper and lower anterior gingivae in respect of liability to haemorrhage on digital pressure, but in the second study the difference was much less marked owing to increased incidence of maxillary bleeding. For example, the group of boys of the first investigation showed nearly six times as many haemorrhagic regions in the lower as in the upper jaw, while in the two groups of the second the frequency in mandibular was less than twice that of the maxillary regions in spite of the slightly increased incidence of the former. These differences may have been related to the season of the year and the relatively high incidence of upper respiratory tract infections, such as the common cold, in the second investigation. There was also a slight variation in age distribution between the subjects of the two studies, those in the second being about one year younger, but there is no reason to suppose that this small difference was of any significance.

#### Incidence of Tartar

In the first investigation 85.7% of the lower but only 23.4% of the upper anterior teeth showed evidences of tartar deposition. In the second study (both groups together) the respective percentages were 94.9 and 12.0. Both soft and hard varieties of dental calculus were included on the examination charts and, since it is difficult to differentiate between the former and food debris, the only possible comment is a suggestion that in the second study tartar was rather less prevalent on the upper teeth; no significant differences were apparent for the mandibular teeth. It would seem clear, however, that the increased incidence in haemorrhage from the upper gingivae (see previous section) was certainly not paralleled by greater prevalence of tartar on the adjacent teeth.

#### Association between Tartar Deposition and Gingival Haemorrhage

For the lower jaw, at least, both investigations provide ample evidence in favour of such an association, as shown by the following findings:

- 1st Investigation.*—Of the 64 lower gum regions with *no* bleeding 43 (67.2%) had little or no tartar on the adjacent teeth;
- 2nd Investigation.*—Of the 66 lower gum regions (both groups of boys) with *no* haemorrhage the figures were 3 (59.1%).
- 1st Investigation.*—Of the 48 lower gum regions showing *positive* bleeding only 12 (25.0%) were free or almost free from injury by tartar;
- 2nd Investigation.*—Of the 72 lower gum regions (both groups of boys) with *positive* haemorrhage the respective figures were still lower—6 (8.3%).

With regard to (a), there was little difference between the pre-test findings of the two investigations ( $\chi^2=0.600$  and  $5 > p > 3$ ), but consideration of (b) indicates a closer association between presence of tartar on the teeth and liability of the adjacent gum to haemorrhage in the subjects of the second study ( $\chi^2=5.035$  and  $0.05 > p > 0.02$ ). It is possible that in the later investigation the encroachment of tartar on to and beyond the gum margin was more extensive, or that the resistance of the gum tissues to such injuries was less. For the upper jaw the low incidence of gingival bleeding (7.2%) in the first investigation and of tartar deposits (12.0%) in the second study precluded testing of the association of such conditions with any degree of accuracy. Moreover, as indicated earlier, in the second investigation the much higher incidence of gum haemorrhage in the upper jaw was not accompanied by an increase in tartar deposition.

#### Mouth-breathing

In the first investigation 9 of the 19 boys were affected by nasal stenosis of tonsillar and/or adenoidal origin before the cane-gnawing was started; none were then suffering from coryza. In the second investigation 14 of the 23 boys (7 in each group) had some nasal stenosis accompanied by coryza at the pre-experimental examination; 8 of these were chronic mouth-breathers (5 in the experimental and 3 in the control group).

#### Dental Caries; Abnormal Alignment and Occlusion

The possibility that any of the observed gingival lesions might have been related to injury of the gum margin by cervical or interstitial caries of the adjacent teeth was discounted by the absence of caries of the anterior teeth in all of the boys of both investigations before and during the experimental period.

Varying degrees of labioversion, linguoversion, and torsion of the incisors and canines were seen in most subjects, and abnormal positioning of the premaxilla and mandible was a common feature. In general, gingival lesions were more prevalent when such conditions existed. In neither jaw, however, did there appear to be any significant difference in incidence or degree of positional or occlusal abnormalities between the three groups of boys.

#### 2. Effects of Gnawing Sugar-cane, with or without Dental Scaling, on Non-ulcerative Gingivitis

*Dental Hygiene.*—Rapid improvement in cleanliness of the anterior teeth and interdental spaces was one of the first effects of gnawing sugar-cane, especially if the latter was in the raw state. This was noticeable, to the patient as well as to the observer, within a short time of the initial application of cane to the teeth. The effect was particularly obvious when preliminary dental scaling was carried out, but was also apparent when raw cane alone was used. In the latter case, however, the degree of cleansing of the

teeth was largely dependent on the extent to which cane could dislodge calculus and other deposits. Further improvement in dental hygiene occurred in the sugar-cane groups as the tests approached the eighth, and final, week of observation. On the other hand, the control group, while showing improved hygienic conditions for the first few days after scaling, rapidly reverted to their previous dirty state, and by the end of the experimental period most of the boys were worse than before. It should here be stressed that there was an almost complete lack of *personal* dental hygiene on the part of the subjects of all three groups.

**Gingival Haemorrhage.**—In confirmation of the previous report another very early response of diseased gum to sugar-cane was relatively profuse bleeding and slight soreness for about the first three days during the actual process of cane-gnawing. After this period the great majority of formerly susceptible gum regions rapidly ceased to be sore or to bleed either from the impact of sugar-cane or on firm digital pressure. For the boys receiving cane supplements, in the lower jaw at least, these findings held good in all studies irrespective of the method of cane preservation or of preliminary dental scaling. Little or no improvement could be determined in the control group, which received treatment in the form of scaling only (see Table). For example, the percentage decreases in haemorrhagic regions in the lower jaw at the end of the experimental period were:

1st Investigation.—After sugar-cane only	34.0
2nd Investigation.—After scaling + sugar-cane	40.9
After scaling only (controls)	11.9

In the *upper* jaw, however, the differences between the cane and control groups were not so marked, although the former in the second investigation showed more than three times the slight improvement of the controls, the percentage decreases in bleeding regions being:

1st Investigation.—After sugar-cane only	5.4
2nd Investigation.—After scaling + sugar-cane	15.4
After scaling only (controls)	4.4

**Colour, Contour, and Texture of the Gingivae.**—As described in the earlier report, when raw sugar-cane alone was employed the degree of gingival recovery varied according to the extent to which the cane could dislodge the tartar and food debris from the cervical and approximal surfaces of the adjacent teeth and from the interdental spaces. Evidence of these changes could be seen in the clinical condition of the gum surface and in the microscopic appearance of the gingival capillaries (King, 1947a, 1947b). For example, under favourable conditions previously diseased tissue passed through various colour gradations from bright red to bluish red and finally to the pale pink associated with health; the glazed texture became matt and then stippled; and swollen, pocketed, and "everted" gingival margins became tightly rolled and finally thin and tapered towards the teeth. Such surface alterations were associated with certain well-defined changes in the epithelium and corium beneath and followed closely those observed in the parodontal tissues of the ferret (King, 1944; King and Glover, 1945). With the addition of preliminary scaling of the teeth it was hoped that sugar-cane therapy would hasten or accentuate these signs of recovery. However, when this possibility was put to the test, using *canned cane*, the response was not as good as anticipated. Nevertheless definite epithelial defence reactions were seen in the sugar-cane groups, while the controls not only showed no such resistance but, indeed, became progressively worse a few weeks after the scaling.

**Tartar Deposition.**—The first investigation demonstrated the removal of relatively soft tartar deposits from the and interstitial surfaces of the anterior teeth. The more adherent accretions were only slightly affected by friction with the sugar-cane, but certainly no increased amount of tartar could be detected during the eight week experimental period. A striking feature of the second investigation was the extremely rapid recurrence of calculus on the lower anterior teeth, particularly the incisors. Within three to four weeks of dental scaling appreciable amounts of fairly hard yellowish-brown tartar were observed. In the sugar-cane group these were almost entirely confined to the lingual and, to a lesser extent, the approximal aspects of the tooth necks—areas relatively inaccessible to the cane fibres; the labial tooth surfaces were comparatively free from deposits. In the control group the formation of tartar was, if anything, still more rapid, and was seen on labial as well as lingual and approximal aspects of the lower teeth.

**Mouth-breathing and Coryza.**—In the first investigation 9 of the 19 experimental subjects were chronic mouth-breathers, but none suffered from the common cold during the period of observation. In the second study all of the 21 boys (both groups) had colds for some part, and many for the whole, of the test period.

### 3. Other Studies in Progress

Sugar-cane, both raw and canned, is being used in the parodontal department of King's College Hospital when supplies are available. In accordance with the experience gained with institutional and other subjects elsewhere, the general procedure comprises the use of cane-gnawing as an adjunct to the more usual forms of gum treatment and mouth hygiene. *Non-ulcerative* lesions associated with dirt and tartar are treated by scaling and one or two applications of 3% chromic acid plus hydrogen peroxide irrigation before beginning cane therapy. When considered necessary, gingivectomy and extraction of loose, maloccluding, or functionless teeth are carried out. In cases of gingival ulceration, such as Vincent's disease, penicillin lozenges, 3% chromic acid plus hydrogen peroxide, and scaling are first employed to eliminate pain and eradicate the bulk of the necrosed tissue and other debris, sometimes supplemented by internal administration of nicotinic acid or nicotinamide. In short, cane-gnawing is used solely to apply friction to the teeth and interdental spaces for cleansing purposes and to the healing gum for stimulating epithelial defence reactions and recovery of health.

### Discussion

I have previously laid stress on the empirical nature of some of the procedures adopted for treating gingival disease and have ample clinical evidence that the over-enthusiastic use of drugs and of surgical intervention (gingivectomy) does in fact play no small part in producing a further breakdown in parodontal health, curable only by extraction of teeth. There is urgent need for reducing the frequency and strength of local applications of escharotics (chromic acid, copper sulphate, silver nitrate, phenol), of astringents (zinc sulphate, zinc chloride, tannic acid), and of oxidizing agents (hydrogen peroxide, sodium perborate). In this respect, at least, sugar-cane therapy if introduced at a relatively early stage, may help to relieve the necessity for these more dangerous forms of treatment.

At the same time the underlying purpose and the limitations of cane-gnawing must be borne in mind. It is of value as a cleansing agent, for stimulating tissue resistance

TABLE II.—Complement-fixation Titres of Normal Human Sera against Influenza Virus B

Titre	Series				Total
	1 Northampton, 1943 (Hoyle, 1944)	2 Northampton, Jan., 1946 (Hoyle, 1946)	3 Northampton, Autumn, 1946	4 Manchester, Autumn, 1946	
1:16 .. ..	0	0	1	2	3
1:8 .. ..	4	2	3	14	23
1:4 .. ..	8	2	33	57	94
1:2 .. ..	9	3	40	65	117
Doubtful (1:2) ..	9	3	16	18	46
Negative .. ..	19	32	157	55	263
Total .. ..	46	45	250	107	448

doubtful or negative readings. Only about 1% of the sera gave titres of 1:16 or higher. Table II shows the results of similar tests with virus B. Of 448 sera examined, 31% gave positive and 69% doubtful or negative readings. Less than 1% of sera gave titres of 1:16 or higher.

The age distribution of antibody against virus A was studied by Fairbrother and Hoyle (1937) and by Martin (1940). It was shown that children under 6 months old showed a similar antibody distribution to adults (presumably maternal antibody is transmitted to the infant), but that after 6 months it was unusual to find antibody in the sera of young children. The incidence of positive sera increased with advancing age.

#### Complement-fixation Titres of Convalescent Sera

The complement-fixation titres of convalescent sera in live epidemics of influenza due to virus A and one epidemic due to virus B are shown in Table III. Similar results were

TABLE III.—Complement-fixation Titres of Influenza Convalescent Sera

Titre	Virus A Epidemics					Virus B Epidemic	Total
	1 Leningrad, 1936 (Fairbrother and Hoyle, 1937)	2 Manchester, 1937 (Hoyle and Fairbrother, 1937)	3 Northampton, 1943 (Hoyle, 1944)	4 Haddington, 1946 (Hoyle and Lyell, 1946)	5 Northampton and Manchester, 1947	6 Northampton and Manchester, 1946

1:128	0	0	1	0	2	3	6
1:64	0	13	2	2	2	4	23
1:32	1	13	2	2	2	2	22
1:16	1	13	4	4	4	0	26
1:8	1	11	4	5	6	1	28
1:4	1	5	2	0	6	0	14
1:2	0	0	1	0	3	0	4
Doubtful (1:2)	0	0	0	2	0	1	3
Negative	0	0	0	1	2	0	3
Total	5	65	14	13	30	11	138

obtained in all six outbreaks. Over 95% of convalescent sera gave positive complement fixation with the infecting virus, and 64% gave titres above the normal limits—that is, 1:16 or higher. The test differentiated sharply between virus A and virus B: thus in the A epidemics the convalescent sera showed an increased titre to virus A antigen but titres against virus B were within the normal range,

and the converse was true in the B epidemic. Fairbrother and Martin (1938) studied the rate at which the high titres in convalescent sera returned to normal. A rapid fall in titre took place in the six months following infection, and by one year all the titres were within the normal range.

The above results show that the complement-fixation reaction can be a valuable diagnostic test in influenza. The test has been positive in over 95% of 138 convalescent sera, and it is interesting to note that the few negative or doubtful results almost all occurred in the very mild outbreaks of 1946 and 1947. The severe epidemics of 1937 and 1943 gave 100% of positive results. In fact a negative complement-fixation reaction in a convalescent serum tends to exclude the diagnosis of epidemic influenza. Over 60% of convalescent sera give titres of 1:16 or higher, while these titres are found in less than 1% of normal sera, so that a titre of 1:16 or higher is practically diagnostic of recent infection.

It is to be noted that figures comparable with the above cannot be obtained by the red-cell agglutination inhibition test. Both normal and convalescent sera show enormous variations in titre by the Hirst test according to the strain of virus used, so that no normal base-line can be drawn and it is impossible to decide whether a given titre in a convalescent serum is diagnostic of infection. To make a diagnosis of influenza by the Hirst test it is essential to examine two samples of serum—one collected at the onset of disease and the other during recovery—in order to demonstrate a rise in antibody titre. The test is therefore much less convenient and reliable than the complement-fixation test.

#### Comparison of the Complement-fixation Test and the Red-cell Agglutination Inhibition Test

The Hirst test has been much used in the diagnosis of epidemic influenza, but it became evident in recent years that the results were inferior to those of the complement-fixation test. It was at first thought that this inferiority was due to antigenic differences between the strain of virus used in the Hirst tests and that responsible for the infection, and that better results would be given if the homologous virus could be used. Experience in 1946-7, however, has shown not only that this is not so but also that the homologous virus may in fact be less suitable for use in the Hirst tests than other strains.

During the last year paired samples of blood serum from acute and convalescent cases of supposed influenza have been examined at the Northampton Public Health Laboratory. Some of the samples were received before the mild outbreak of influenza which occurred in the winter and were almost certainly not from cases of influenza. The sera were tested by complement fixation and by red-cell agglutination inhibition, using six different strains of virus A. The Salk (1944) modification of the Hirst test was used. A fourfold increase in antibody titre was taken as diagnostic of infection. The results are given in Table IV.

TABLE IV.—Comparison of Complement-fixation and Red-cell Agglutination Inhibition Tests in the Diagnosis of Epidemic Influenza (Virus A)

Total pairs of sera examined	14
Total positives (i.e., positive by any one or more tests)	14
Positive by complement-fixation test	14
Positive by red-cell agglutination inhibition tests with:	
P.R.8 virus	12
Swine virus	11
Barratt virus	11
Melbourne virus	11
D.S.P. virus	11
W.S. virus	11

The complement-fixation test shows an obvious superiority over the red-cell agglutination inhibition test. In the Salk tests the best results were given by the P.R.8

and swine viruses. The Barratt strain, received from Dr. C. H. Andrewes, was actually isolated from the mild epidemic of 1947; but gave results inferior to P.R.8 and swine viruses. It is of interest to note that the worst results in the Salk tests were given by the W.S. strain of virus; it was from this strain that the preparation of complement-fixing antigen used in the fixation tests was made. Table V

TABLE V.—Quantitative Increase in Antibody Titre in 18 Cases of Influenza Virus A Infection as Measured by Complement-fixation and by Red-cell Agglutination Inhibition Tests

Increase in Titre	Complement-fixation Test	Red-cell Agglutination Inhibition Tests					
		P.R.8	Swine	Barratt	Melbourne	D.S.P.	W.S.
<128	4	0	1	0	0	0	0
x 64	2	0	1	0	0	0	0
x 32	2	1	3	1	1	0	1
x 16	4	2	0	3	2	0	2
x 8	2	5	4	0	3	3	2
x 4	2	5	3	7	5	7	3
x 2	1	1	4	2	2	0	4
No increase	1	4	2	5	5	8	6

shows the quantitative increase in titre of the positive sera measured by the complement-fixation test and by the six different Salk tests. In general the increase in titre as a result of infection was greater in the complement-fixation test than in the red-cell agglutination inhibition tests.

#### Increase in Antibody Titre as a Result of Vaccination

The rise of antibody titre as a result of the prophylactic inoculation of a vaccine containing a concentrated suspension of virus A of Australian origin was tested in 16 individuals, using the complement-fixation test and Salk tests with P.R.8 and Melbourne viruses. The results are shown in Table VI. Considerable individual differences

TABLE VI.—Quantitative Increase in Antibody Titre in 16 Individuals Vaccinated against Influenza A Virus

Increase in Titre	Complement-fixation Test	Red-cell Agglutination Inhibition Tests	
		P.R.8 Virus	Melbourne Virus
<128	0	0	1
x 64	0	1	1
x 32	0	1	0
x 16	0	2	0
x 8	1	3	3
x 4	4	4	6
x 2	5	2	1
No increase	6	3	4

occurred in the response to the vaccine. The rise of antibody titre was greater when measured by the Salk test than by the complement-fixation test. The antibody response to vaccination therefore differs from that due to infection. In infection the body is exposed to large amounts of both virus and soluble antigen and reacts to both stimuli. The vaccine, however, contains only small amounts of soluble antigen, and the antibody response is therefore small when measured by the fixation test.

#### Discussion

The most striking feature of the red-cell agglutination inhibition test is its strain variability. Results obtained with one strain of virus A may differ completely from those obtained with a different strain. This phenomenon is even more marked with strains of virus B. This strain variation renders the test unsuitable for the serological diagnosis of epidemic influenza, since the results are dependent on a chance antigenic relationship between the infecting virus and that used in the tests. By contrast the complement-fixation test is species-specific, distinguishing sharply between virus A and virus B but giving identical results with individual strains of virus A or virus B. On theoretic

cal grounds, therefore, the complement-fixation test should be more suitable for the serological diagnosis of epidemic influenza, and the work described in this paper shows that this theoretical superiority is in fact observed in practice.

In view of the considerable differences in antigenic structure between different strains of both virus A and virus B, the question arises what degree of difference from the classical strains would lead to a virus being regarded as a new species. We would suggest that the essential species characteristic is the soluble antigen. Any virus having a soluble antigen identical with that of the classical W.S. strain should be regarded as a strain of virus A, while any virus having soluble antigen identical with that of the Lee strain should be regarded as a strain of virus B.

The position of the swine virus is of interest in this connexion. On serological grounds there is no reason to regard the swine virus as anything other than a strain of virus A. Its soluble antigen is identical with that of the W.S. virus, and even in red-cell agglutination inhibition tests it is at least as satisfactory an antigen for the diagnosis of human infections as any human strain available. It might be maintained that the swine virus differs from other strains of virus A in being avirulent for man, but in this respect it does not differ from the majority of laboratory strains, which as a result of adaptation to mice or fertile eggs have lost human virulence. If the soluble antigen is regarded as the essential species character, then the complement-fixation test becomes the essential criterion for the diagnosis of influenza outbreaks. It has obvious advantages for this purpose. The range of complement-fixation titres of normal human sera is remarkably constant at a low level, while the majority of convalescent sera show titres above the normal range. It is advisable to examine two sera (acute and convalescent) from each patient, but a diagnosis of epidemic influenza can often be made by the examination of convalescent serum only.

The increase in antibody titre as a result of infection is generally greater when measured by the complement-fixation test than by the red-cell agglutination inhibition test, while the complement-fixation titres of normal sera are not greatly influenced by prophylactic vaccination. Moreover, the complement-fixation test presents no special technical difficulties, and we have obtained strictly comparable results even when working in different laboratories. Results obtained over a period of ten years also seem to be exactly comparable.

#### Summary

The results of complement-fixation tests on normal sera and the sera of influenza convalescents over a period of ten years are described.

The complement-fixation titres of normal human sera are very constant at a low level, while the majority of convalescent sera show titres above the normal range.

The complement-fixation test is species-specific, distinguishing between virus A and virus B, but shows no strain specificity such as is seen in the red-cell agglutination inhibition test. The complement-fixation test is therefore superior to the red-cell agglutination inhibition test for the serological diagnosis of epidemic influenza.

The complement-fixation test is not suitable to assess the antibody response to vaccination with influenza virus.

## THE GENERAL PRACTITIONER AND THE INFLUENZA PROBLEM

BY

C. H. STUART-HARRIS, M.D., F.R.C.P.  
 Professor of Medicine, University of Sheffield

The general medical practitioner undoubtedly is closely concerned with the problem of human sickness attributable directly or indirectly to the operation of the influenza viruses. Long before the statistician has decided that an influenza epidemic has begun in the population, the practitioners in at least some parts of the country have begun

to experience the well-recognized phenomena of crowded surgeries and long lists of sick people who require to be visited. There is no doubt that, if a solution of the problem of influenza could have been reached by mere clinical observation alone, someone concerned in actual general practice would have been the most likely person to suggest the remedy. As it is, however, mere clinical observation failed to distinguish any clear light in the darkness which enveloped the whole subject of influenza prior to the nineteen-thirties, when the first clues of the influenza viruses of animals and of man were picked up in the laboratory.

Now, laboratory workers concerned with the influenza viruses have always recognized the fact that influenza is a disease which lies peculiarly within the province of the general practitioner. Whenever opportunity has presented, the laboratory findings and problems, both solved and unsolved, have been laid before practitioners in the traditional manner. If it had not been for the great practical difficulties connected with the laboratory technique needed to prove the existence of human influenza virus infection, patients under the care of general practitioners would have been chosen for investigation instead of individuals in the Services, school-children, and others who were in fact investi-

gated. Nevertheless, though few direct tests have ever been made on subjects from a general practice, as knowledge has grown it has become clear that information furnished by the practitioners of this country has an important part to play in the general study of the epidemiology of influenza. The information referred to is that supplied in the form of notifications of deaths from influenza in the great towns of England and Wales. The manner in which this information has been correlated with the isolation of influenza virus from actual outbreaks of influenza or with serological tests has been referred to in detail on several occasions (Stuart-Harris, 1945, 1947). Briefly, the facts are that in the last ten years, whenever practitioners have notified 100 or more deaths from influenza in one week, laboratory workers have been able to obtain evidence that one or other of the influenza viruses is concerned in the causation of outbreaks of the disease in what are usually termed semi-isolated communities—i.e., schools, hospitals or Service establishments. The years when the deaths never rose above 100 a week have also failed to supply the laboratory with evidence of virus infection. Furthermore, the laboratory worker has been able to correlate the type of curve obtained from plotting the figures of deaths from influenza with the type of virus concerned in the outbreak. Thus the sharp peaks reaching 1,000 or more in a week

have been associated with influenza virus A. The less peaks between 1 and 500 have been associated with either or both the two viruses A and B. These facts are shown in graphic manner in the accompanying chart.

Such facts were at once suggested that influenza virus infection in the general practitioner is clinically recognizable. At the same time it became clear that some of us have studied patients of actual outbreaks of influenza infection in the general practitioner and that the individual is recognizably and clinically

Chart showing number of influenza deaths in the great towns from 1933 to 1947, together with the causative virus.

other acute infections of the respiratory tract. Further the cases which are notified as deaths from influenza fatalities, whereas influenza is in the vast majority of cases a benign disease. Thus it has come about that of us who have been concerned with research on the prevalence of influenza in this country are continually puzzled, all, why fatal cases of the human disease should be correlated with influenza virus infection, and, secondly, to know what sort of disease is constituted by this notification of a "fatal case from influenza." The puzzle has not been merely that of armchair speculative type but has concerned us with the imperfection of our knowledge of the extent of damage caused by the influenza viruses. We know that virus is causative of that type of clinical picture cor-

med uncomplicated influenza and probably of the complication of basal bronchiolitis. We also know that the case of acute rapidly spreading pneumonia with helio-cyanosis is associated with a staphylococcal infection of the lung combined with an influenza virus infection. Yet the relationship between influenza virus infection and the ordinary case of pneumococcal pneumonia seen during outbreaks is obscure. Indeed, the actual patient has usually given negative results when tested for evidence of influenza virus infection at the time of admission for treatment of the pneumonia. If we knew whether such cases were in fact initiated by influenza virus infection, even if the subsequent pneumonia was due to pneumococcal infection permitted by the weakened defence of the respiratory tract, we should also know whether to expect that control measures such as immunization with influenza virus vaccines would prevent "deaths from influenza."

It seems, therefore, that more knowledge concerning the complications of influenza, and particularly of fatal cases, is needed. Such knowledge is not likely to be gained by investigation of the localized outbreaks of the disease such as those studied thus far, for complications of any character in the populations ordinarily affected are uncommon. Obviously this is due to the type of subject affected, who is usually a previously healthy young adult or child. When a full-time department of medicine of the University of Sheffield came into being in 1946 we decided to attempt to study this problem from a different angle. In view of the fact that deaths from influenza must often occur in hospital, it seemed to us probable that a cross-section of the ordinary hospital cases of pneumonia admitted during an outbreak of influenza would be likely to include cases of a type familiar to practitioners and attributed by them to influenza. The department has clinical facilities both the voluntary and the municipal hospitals of Sheffield, and thus is in a position to study such cases.

Last winter a number of explosive outbreaks of influenza occurred during January in Army camps housing German prisoners-of-war in the Midlands. From each of three outbreaks Dr. Margaret H. Miller was able to recover strains of an influenza virus and identified the serological response in cases of the disease as that found in influenza A. The general public at this time was largely unaffected, though the deaths from influenza rose and reached a peak in the first week of February and workers at the National Institute for Medical Research (Dudgeon *et al.*, 1947) identified influenza A outbreaks in the South of England.

Though the weather was very severe in the Sheffield region fewer cases of pneumonia than the average were admitted to hospital during the winter. An analysis of the work of several general practitioners in the Sheffield area was carried out by Dr. J. Pemberton; this showed, however, that 30 to 50% of their work during the first week of February was concerned with diseases of the respiratory tract. Dr. A. Dick studied the clinical features and bacteriology of some 40 cases diagnosed as pneumonia and admitted under my care during January, February, and March. The patients were often only mildly ill, their illness responded in the usual way to chemotherapy, and none died. Pneumococci were, however, usually identified in the sputum, including pathogenic organisms such as types I, II, VII, and VIII. A few tests of sputa from such patients were made by Dr. Miller with the technique which was successful in the case of the influenza patients, but virus strains were not obtained. Yet the serological tests on the cases of pneumonia suggested that many of the patients admitted in January and February had in fact suffered from

an infection with influenza virus A at some time shortly before or during the pneumonic episode. The results surprised us and, largely because of their unexpected character, we failed to establish by adequate control studies the crucial point of whether, so far as the virus was concerned, the patients with pneumonia were in any way different from Tom, Dick, or Harry of the general population. In other words, the influenza A of last winter might have affected a similar proportion of individuals in the general public as in the cases of pneumonia by an unusually widespread subclinical infection, even though the "epidemic" seemed to be restricted clinically to certain community groups. It thus remains for us to repeat the study during future outbreaks in order to determine whether cases of ordinary pneumococcal pneumonia at the time of influenza outbreaks are or are not related to the virus infection. Because of the periodic character of influenza outbreaks, this work will probably take some years to complete.

Meanwhile, however, it seemed to us possible to collect together useful information concerning the cases which are actually notified by practitioners as "deaths from influenza." Only in this way will it be possible to decide whether mortality from influenza is particularly liable to occur in any one section of the population. It may be worth while pointing out in this connexion the probability that heart failure may be precipitated by influenza virus infection. An example of such a case is given below; this would have been regarded as that of ordinary bronchopneumonia and congestive heart failure had it not been for the serological results, which clearly implicated influenza virus A. It is possible, therefore, that this investigation may reveal information of value in connexion with a variety of topics, and may supplement the observations made on our own patients. It will be particularly important, for instance, to ascertain whether there are any clinical differences between deaths from influenza notified in years when influenza virus infection is not identified and those occurring in years when the viruses are active.

In order to provide sufficient material for statistical analysis within a reasonable period of time it will clearly be necessary to collect data from many sources. The more detailed clinical and laboratory observations possible on patients in hospital will then furnish a useful collateral study to the wider investigation which is proposed.

### Case Report

A man aged 52 was admitted on Jan. 24, 1947, in a condition of great restlessness, with a history of cough and dyspnoea for about four weeks, increasing greatly in the four days before admission. He presented signs of hypertensive heart disease with congestive failure, though there was as yet no oedema. Rhonchi were heard in the lungs and over the left base, which was slightly impaired to percussion; there were numerous rales. There was a low irregular fever (98-100° F. (36.7-37.8° C.)) for three days, accompanied by tachycardia (100-110) and a slightly increased respiratory rate (20-26). After four days the restlessness had if anything increased, the signs in the lungs persisted unchanged, and orthopnoea was present. Skiagrams by portable apparatus showed congestion at both lung bases and considerable cardiac enlargement. Inoculation of the sputum into mice yielded a pneumococcus which could not be typed. Treatment with penicillin was begun, and continued for nine days. A week later the general condition had improved, but venous congestion had increased, sacral oedema had appeared, and the heart sounds showed a triple rhythm. The blood pressure had risen from 160/85 on admission to 185/120. There was no further deterioration, but the heart failure was slow to respond to therapy by digoxin and venesection, and basal rales persisted at both lung bases. Further treatment with diuretics was followed by slow improvement and the patient was

discharged on March 28 in reasonable health though still with cardiac enlargement and hypertension. The serum antibodies to the PR8 strain of influenza virus A and the Lee strain of virus B were estimated in samples collected on admission (Jan. 25) and on Feb. 15 by the agglutination-inhibition test (Hirst). The results showed that the antibody level against influenza virus A had increased 64 times during the progress of the patient's illness, whereas that against influenza virus B had remained unchanged.

## AMOEBI ABSCESS OF THE LEFT BUTTOCK IN A SYMPTOMLESS CYST CARRIER

BY

Air Commodore T. C. MORTON, M.D., F.R.C.P.  
D.T.M.&H.

AND

Squadron-Leader S. F. SOUTAR, M.B., F.R.C.S.Ed.

(From the R.A.F. Institute of Pathology and Tropical Medicine, Halton)

Cutaneous amoebiasis has been reported from many parts of the world. The cases fall into five groups according to their connexion with other primary conditions: (1) those following the drainage of an amoebic abscess of the liver (Heimbürger, 1925); (2) those following the drainage of a lesion of the appendix (Cole and Heideman, 1929); (3) those following a colostomy for a rectal obstruction (Smyth, 1946); (4) those about the anus associated with amoebic colitis (Van Hoof, 1926); and (5) those without any direct connexion with the viscera.

In practically all of these cases motile entamoebae were found in fresh preparations from the lesions of the skin. The case described below falls into the last category. The only references we can find in the literature that are at all analogous to our case differ from it in some respects; these will be discussed later. Van Hoof (1926) reported the case of a negro woman who suffered from dysentery in 1915 for which she received injections, probably emetine, but was not cured. In July, 1925, multiple ulcerations appeared on the skin of the buttock and around the anus, some of the ulcers communicating with the bowel. In the pus of both the fistulous ulcers and those not communicating with the rectum active entamoebae containing red blood cells were found; after specific treatment with emetine the amoebae could no longer be demonstrated and the lesion healed rapidly. In our case there was no history of previous dysentery, and the most careful search failed to reveal any direct communication with the rectum.

Ngai and Frazier (1933) described a case in which a papilloma of the anal region was invaded secondarily by *Entamoeba histolytica*. We believe that a secondary invasion of a staphylococcal abscess occurred in our case. This is reported, as, apart from the rarity of the condition, it is felt that similar cases may arise during the next few years in Service personnel, and unless the condition is recognized at an early stage gross destruction of the tissue will occur as in the case reported by Norwich and Muskat (1946). Their case occurred in a negro, who gave a history of a small blind boil appearing near the anus which eventually burst and instead of resolving was followed by a rapidly spreading ulceration. There was a previous history

of colicky lower abdominal pain and diarrhoeal stools with occasional blood. On his admission to hospital an ulcer measuring 5 in. by 2 in. (12.5 cm. by 5 cm.) was present on the left buttock, extending obliquely across the sacrum to the opposite buttock. Sigmoidoscopy revealed a large necrotic ulcerating area covering the posterior wall, while a biopsy from the edge of the ulcer of the skin revealed the presence of numerous *E. histolytica*. A colostomy had to be carried out to prevent soiling of the ulcerated area, but eventually, after specific anti-amoebic therapy followed by a skin graft, complete healing occurred.

This case differs from ours in that there was gross ulceration of the rectal mucosa. An extensive search through the literature has failed to reveal an exactly parallel case to the one here recorded.

## Case Report

A warrant officer aged 27, of excellent physique, was admitted to an R.A.F. station sick quarters on Jan. 4, 1947, with a painful swelling on the left buttock which had been discharging pus for five days. He stated that he had had some pain in the left buttock about four months previously and that there was a swelling in this region. Apart from pain on sitting this gave no trouble and did not interfere with his normal activities. On Dec. 29, 1946, the swelling burst and discharged pus, and after this the pain increased in severity and he reported sick.

**Previous History.**—In September, 1945, he was kicked in this area while playing football in Bombay, where he had served for two years. He returned to the United Kingdom in October, 1946, and three weeks later he first noticed the pain in his buttock. He had never had dysentery, and remembered only one mild attack of diarrhoea, lasting one day, during his tour abroad.

**Present Illness.**—He was transferred to an R.A.F. station hospital on Jan. 4. On examination a slight bilateral inguinal adenitis and a swelling of the left buttock some 4 in. by 4 in. (10 cm. by 10 cm.) were found. This swelling was hard centrally but soft and fluctuating peripherally; pus was escaping from a small opening, and probing of this opening revealed a short sinus some 3/4 in. (1.9 cm.) long. Pus from the sinus grew *Staphylococcus aureus* and *albus*. His B.S.R. was 40 mm. in one hour. A skiagram of the lumbar spine and pelvis revealed no abnormality. The skin showed dark purplish discoloration. The W.R. and Kahn test were negative. The abscess was incised on Jan. 8, and two main cavities were found communicating with each other and lying subcutaneously; there was no sign of any communication with the rectum. Histological examination of the curettings revealed granulation tissue with aggregations of plasma cells scattered among the polymorphonuclears; there was no specific evidence of tubercle or actinomycosis. After the operation short-wave therapy and the instillation of 100,000 units of penicillin on alternate days led to considerable local improvement, and the abscess cavity appeared to be granulating satisfactorily. On Jan. 18 further undermining of the skin laterally led to pocketing of pus and the appearance of fresh sinuses.

Local treatment having failed it was decided to try the effect of systemic penicillin, and a million units were given over five days without any response. The failure of any form of treatment and the unusual features of the ulcer then suggested that it was a fungous infection (? sporotrichosis), and iodides were given for several days, again without any noticeable improvement.

By Feb. 19 the ulceration had spread both medially and laterally, and fresh sinuses had appeared near the medial edge. The abscess had to be re-incised on Feb. 21, and the gelatinous material was curetted from the sinuses, but the cultures were sterile. Histological examination of the material from the curettings revealed an oedematous granulation tissue infiltrated with plasma cells and macrophages and scanty cells which resembled *E. histolytica*. The patient was transferred to Princess Mary's Royal Air Force Hospital for further investigation. Examination showed a granulating ulcer measuring

2½ in. by 1½ in. (6.25 cm. by 1.25 cm.) with an overhanging undermined edge on the inner wall; internal to this there was a dusky, devitalized area of skin with three sinus openings close to the natal cleft, superior, and one 3 in. (7.5 cm.) lower down, inferior. A probe could be passed from each of these sinuses for from 2 to 3 in. (5 to 7.5 cm.) emerging below the undermined edge of the ulcer. Curettings from the walls of these sinuses revealed actively motile *E. histolytica*, many of them with ingested red blood corpuscles. In view of this positive finding it was not considered justifiable to carry out a biopsy. Sigmoidoscopy to 25 cm. revealed a normal mucosa, except for the presence of two pin-point petechiae on the anterior wall of the rectum; no communication or induration that suggested a fistula could be felt, and pressure on the left wall of the rectum revealed no tenderness and did not lead to any discharge from the external sinuses. *E. histolytica* cysts were present in the faeces in small numbers. A course of emetine, gr. (65 mg.) intramuscularly for ten days, together with "diiodoquin" three tablets t.d.s. by mouth, was completed. At the end of this course the condition had greatly improved; the pain, swelling, and discharge had disappeared, but it was still possible to pass a probe in various directions beneath the dusky devitalized skin, and it was decided to lay open and excise the sinuses.

The operation was carried out by Squadron-Leader Pike on Feb. 25. On slitting open the sinuses they were found to communicate with each other like an extensive rabbit-warren, and it was considered advisable to excise the whole devitalized skin. The sinuses were found to be entirely subcutaneous and appeared to have spread laterally without penetrating the deeper tissues; there was no evidence of any communication with the rectum. This form of peripheral spread was reported by Ngai and Frazier (1933), who stated: "After reaching the deeper layers of the epidermis the parasites tended to advance along the plane of least resistance between the epidermis and the utis." It was also a marked feature in the case reported by Smith (1946), in which an ulcer involving half the abdominal wall followed an operation for closing a colostomy in an unsuspected case of amoebiasis. A skin graft was carried out on April 21 by Wing-Commander Morley in order to expedite healing, and this was entirely successful. The patient was discharged to duty on May 21.

### Discussion

It is difficult to decide the exact role of *E. histolytica* in the genesis of the abscess. There are three ways in which the abscess may have arisen. (1) By invasion through the blood stream. Although this is possible, Craig (1944) in his unique experience has never heard of amoebiasis cutis. (2) By invasion from the rectum. If the abscess was primarily due to *E. histolytica* it must be presumed that infection occurred through the rectum in a symptomless cyst carrier via a fistulous tract which subsequently healed spontaneously and of which no trace as remained; this is an extremely unlikely occurrence. Norwich and Muskat suggest the possibility of lymphatic spread from the rectum; this is a possibility in our case. (3) By secondary infection with *E. histolytica* in a distorting staphylococcal abscess. This appears to be the most reasonable explanation, and is supported by the negative biopsy findings at the time of the first operation, the initial improvement followed by further spread and sinus formation, and the failure to respond to penicillin. The pathology of amoebiasis cutis has been well described by Hu (1937), and the localization of the amoebae immediately under the skin, together with the peripheral spread, would produce the clinical picture found in this case.

Christophers's *Text Book of Surgery* states: "It seems to the writer that one or all of the following conditions would obtain before it can be fairly stated that amoebae are participating actively in any infection: (1) there should be histological evidence of the invasion of the tissues by

the amoebae, (2) they should be found either by smear or culture in the advancing margin of the lesion, or (3) the lesion should respond to medical treatment recognized as adequate for amoebic disease. The writer believes that the mere presence of amoebae on the surface of the lesion or in the exudate is no more evidence of their participation in the infection than the presence of *B. coli*, *B. proteus*, *Cl. welchii*, or any of the other intestinal organisms is evidence of their activity in the tissues about a faecal fistula." Our case satisfies these three conditions.

### Summary

A case of amoebic ulceration of the buttock in a symptomless cyst carrier is described and the recent literature on the subject is reviewed.

The aetiology of the genesis of the abscess is discussed and the importance of excluding amoebiasis in any lesion of the ano-rectal region is stressed, especially in personnel who have served in the Tropics.

We are indebted to the Director-General of the Royal Air Force Medical Service for permission to publish this paper.

## A CASE OF SEVERE PRE-ECLAMPTIC TOXAEMIA WITH CENTRAL PLACENTA PRAEVIA

BY

GEORGE NEWBOLD, M.R.C.S., D.R.C.O.G.

Lately Resident Obstetric Officer, St. Mary's Hospital, Portsmouth

A married woman, 32 years of age and in her third pregnancy, was admitted to hospital as a moderately severe case of pregnancy toxæmia on March 25, 1946. On admission she complained of some swelling of the ankles and occasional vomiting during the past week or ten days. She had had no headaches, visual disturbances, or pain elsewhere, and her only other complaint was a certain amount of epigastric discomfort caused by indigestion and flatulence which was relieved by a carminative mixture. Her last menstrual period was Aug. 1, 1945.

The patient had two children, now aged 8 and 10 years, and no miscarriages. She had had no illnesses or operations except for some degree of hypertension during the latter part of the second pregnancy.

On examination she looked rather ill and had slight conjunctival pallor. There was some oedema, not marked, of both ankles and the lower parts of both legs. Her blood pressure was 150/100 mm. Hg, and testing the urine revealed a distinct cloud of albumin. The fundus of the uterus corresponded to a height of about 36 weeks' pregnancy and was not tender on palpation. Although it was rather difficult on abdominal palpation to determine precisely the presentation of the foetus it seemed more likely to be a breech rather than a vertex.

The next day, March 27, after starting treatment for toxæmia, which consisted in complete administration of "ostocalcium," "marmex," glucose drinks, and phenobarbital.

(32 mg.) b.d., there was a slight improvement in her general condition and the oedema became less. The blood pressure was then 160/98 mm. Hg, and a catheter specimen of urine still showed a cloud of albumin on testing.

The following day she complained of some blurring of vision, with spots in front of her eyes during the night, and this persisted during the day. She also complained of backache and headache mainly in the frontal region, and her blood pressure rose to 168/110 mm. Hg. In view, therefore, of the sudden deterioration in the patient's condition it was decided to perform a surgical induction forthwith. Artificial rupture of membranes was attempted but had to be abandoned because an unsuspected central placenta praevia was felt completely covering the internal os. There was some slight bleeding on digital examination. The patient was thereupon prepared at once for caesarean section, for this was considered to offer the best chance of survival to both mother and baby.

### Operation

On March 28 at 6.30 p.m. atropine, 1/100 gr. (0.65 mg.), was given. At 7 p.m. a general anaesthetic was started (chloroform 1 part mixed with ether 3 parts). At 7.15 p.m. the abdomen was opened through an incision for a classical caesarean section. As soon as the uterus was reached its anterior wall was seen to be a deep purple in colour, almost the whole of the myometrium being extremely thin—in places almost like paper. It appeared to consist merely of the outer peritoneal covering and a little fibrous tissue and to be in imminent danger of spontaneous rupture. There were many peritoneal adhesions, especially on the anterior uterine wall, and omentum and intestine were also adherent to the uterus. A living female infant, breech presentation (right sacro-anterior) was then delivered. The upper segment of the uterus was separated from intestines and omentum and removed. During this part of the operation the wall of the uterus came apart in fragments when pulled upon by forceps. Hysterectomy was attempted but found to be impossible owing to adhesions, so the remaining lower portion of the uterus was sewn together with a double row of catgut sutures. The placenta, which was of the central variety and almost filled the lower segment, was very disorganized and infarcted in appearance. Towards the end of the operation the patient became shocked and was given oxygen. She was then returned to the ward.

At 8.15 p.m. anti-shock treatment was continued and intravenous plasma started. Soon afterwards the patient began to recover consciousness but was still in a very shocked condition. There was some improvement after one bottle of plasma. At 9 p.m. intravenous transfusion of Group-O Rhesus-negative blood was begun. There were some slight rigors in spite of satisfactory cross-matching.

At 11 p.m. there was marked deterioration in the general condition. The patient became very restless and delirium started. Morphine, 1/6 gr. (11 mg.), was given at 11.45 p.m. At 12 midnight the pulse became very much weaker and the respirations were infrequent, shallow, and irregular. Nikethamide and continuous oxygen were given, but the patient soon became comatose and died.

### Discussion

The sudden change from a moderately severe toxæmia to a condition bordering on true pre-eclampsia, in spite of treatment having been started, after symptoms had been present for only just over a week before admission to hospital is noteworthy. There were present three abnormal conditions, any one of which might have proved fatal, for at any moment immediately before entering hospital the patient might have been overtaken by (1) the sudden onset of eclampsia, (2) a severe antepartum haemorrhage, and (3) a ruptured uterus.

The cause of the low-lying placenta in this case might have been the poor condition of the upper portion of the uterus, with consequent difficulty in nidation of the ovum

in a normal position. The reason for the excessive thinness of the upper uterine segment and the almost complete disappearance of muscle fibres in certain areas was not determined. There was no history of peritonitis or an operation which might have accounted for the many dense adhesions found at laparotomy. So far as the patient herself knew her previous confinements were quite normal, apart from some degree of hypertension towards the end of the second pregnancy. There was no history of pyrexia during the puerperium after the birth of her other children.

The previous hypertension might have contributed to the degeneration of the myometrium, for in women dying from eclampsia areas of myometrial infarction have been found post mortem. Hypertension could presumably lead to a relative ischaemia of the tissues supplied by the affected vessels and perhaps in some cases, if severe enough and prolonged, to their replacement by fibrous tissue. Furthermore, this patient was clinically rather anaemic, although unfortunately a haemoglobin estimation and erythrocyte count were not done. Anaemia would conduce to any degenerative processes which might occur. Another possibility is that there was an undiagnosed partial rupture during one of the previous confinements, although there was no history of any previous dystocia; nor, if the myometrium was then healthy, is there any reason why even a partial rupture should have occurred. Probably, as often in medicine, the cause of this and other morbid conditions will ultimately be found to be a combination of several factors.

I wish to thank Dr. R. A. Zeitlin, Medical Superintendent of St. Mary's Hospital, Portsmouth, who has kindly given permission for the report on this case to be published, and Mr. Trevor Barnett, consulting obstetrician and gynaecologist to the hospital.

## Medical Memoranda

### Abdominal Implantation of Fertilized Ovum

Since examples of implantation of a fertilized ovum in the peritoneal cavity are comparatively rare, the following case may be of some interest.

#### CASE REPORT

A married woman aged 32 was admitted to the Royal Victoria Infirmary, Newcastle-upon-Tyne, on Jan. 16, 1947, as a case of ruptured ectopic pregnancy. In 1940 she had a normal full-term delivery and her puerperium was uneventful. She had never had a miscarriage, nor could any evidence of previous abdominal or pelvic inflammation be obtained. Her menstrual cycle was regular every 28 days and the period usually lasted four to five days. Her last normal period began on Dec. 10, 1946, and was of the usual duration. She was perfectly well until Dec. 26, when at 1 a.m. she was seized with sudden acute lower abdominal pain which prostrated her and made her crawl about in agony. She remarked that the pain was similar to that of labour. After three hours the pain disappeared suddenly and she felt well again. There was no pain thereafter until Jan. 12 when she had another attack of lower abdominal pain, not so severe as previously, but on this occasion it persisted until Jan. 15, although it was not particularly acute. With the onset of pain, haemorrhage per vaginam was noted, and it continued right up to the time of operation. While reading in bed on the morning of Jan. 16 a further sudden attack of acute lower abdominal pain occurred and she felt very ill indeed. She was seen by her doctor at 6 a.m. and sent into hospital.

On admission the patient looked very ill, with a definite cyanotic tinge of the skin. The temperature was 98.6° F. (37° C.); the pulse was 100 and of poor volume. She complained of generalized lower abdominal pain, and also pain in the right shoulder region and the lower ribs on the right side. Examination showed a diffuse tenderness over the lower abdomen, possibly slightly greater on the right. There was no rigidity and Cullen's sign was absent. Vaginal examination caused the patient much pain, but it was possible to feel a boggy mass in the pouch of Douglas. A lump was not palpable.

Operation was carried out without delay on the diagnosis of suspected tubal gestation. The abdomen was opened through a midline subumbilical incision and was found to be full of blood—in the main fluid, but containing some large dark clots. Both tubes were examined and found to be normal in appearance, as was the right ovary. A small bleeding-point was noticed on the left ovary (possibly due to the points of the dissecting forceps) and was sutured. On clearing away the clots in the pouch of Douglas the ovum was found to be implanted at the bottom of the pouch and slightly to the right, and was about the size of a cherry. There was a steady trickle of blood coming from the implantation site. The ovum was picked up with sponge-holding forceps and dissected clear of the peritoneum by means of a dissector. The peritoneum was fixed with a continuous catgut suture as there was still a little seeping from the raw area. Some difficulty was experienced in this part of the operation on account of the depth of the pouch of Douglas. The abdomen was cleared of blood so far as possible and a further examination of the Fallopian tubes made. To the naked eye and to palpation both appeared normal. The abdomen was closed in layers without drainage. Blood transfusion was started as soon as the abdomen was opened and continued throughout the operation and on return to the ward.

The patient's convalescence was satisfactory as regards her abdomen, but a weakness of the muscles of the left arm and forearm was noticed immediately after the operation, due to over-reliance of the brachial plexus. It was this arm that was used for the transfusion, and the condition was undoubtedly caused by over-contraction of the arm with the patient in the Trendelenburg position. The condition improved rapidly, but there was still some weakness of the biceps when she was discharged from hospital. The tissue removed from the pouch of Douglas had the appearance of chorionic villi, and this was subsequently confirmed by histological examination. The pathologist's report stated: "The material consists of recent blood clot and chorionic villi." An ovum was not found.

#### COMMENT

The interest in the case lies in whether this was a primary or a secondary abdominal implantation. On the visual evidence of normal tubes one is tempted to say that it was indeed primary. A consideration of the history, however, puts a rather different complexion on the matter, and it is almost certain that her first attack of abdominal pain on Dec. 26 was due to the successful efforts of one tube to expel the ovum in its lumen. The second attack of pain and the bleeding per vaginam are more difficult to explain. Only four days elapsed between the onset of the pain and operation, and it seems barely feasible to suggest that the expulsive efforts of the tube on Dec. 26 were not completely successful and that total expulsion did not occur till Jan. 12. Had this been the case one would have expected to find some visual evidence of recent tubal involvement. Furthermore, the ovum was firmly implanted on the peritoneum of the pouch of Douglas, pointing, in my opinion, to a longer "implantation-time" than four days. The available evidence therefore points to this being a case of secondary implantation of a fertilized ovum.

I wish to thank Mr. H. Harvey Evers, honorary gynaecologist, Royal Victoria Infirmary, for permission to publish this case, and the Pathology Department of the infirmary for the histological report.

### A Case of Cerebellar Tumour Simulating Pyloric Obstruction

It is recognized that in cases of intracranial tumour nausea and vomiting may be sufficiently prominent, especially in children, to attract attention to the stomach as the cause of the trouble (Camp, 1925). Bailey *et al.* (1939) mention one case of their own in which appendicectomy had been performed, and two others, reported by Babonneix, which had been treated for some months for enteritis and chronic appendicitis respectively. Cushing (1930) found cyclical vomiting and pyloric stenosis among various erroneous diagnoses of cases which eventually came under his care.

In the following case, owing to the prominence of the gastrointestinal symptoms and the absence of physical signs in the central nervous system, it was thought wise to perform a barium-meal examination to exclude a lesion of the gastro-intestinal tract before subjecting the patient to the more elaborate neuro-

surgical diagnostic procedures. The surprising discovery of a 26-hour delay in the stomach led to the mistaken diagnosis of organic pyloric obstruction.

#### CASE HISTORY

On Aug. 15, 1945, a boy aged 10 was admitted with a six weeks' history of vomiting, occurring each morning within a few minutes of waking up, followed by a frontal headache; this was severe and usually lasted 10 to 20 minutes but occasionally persisted till midday. The vomiting sometimes recurred during the morning, but it, too, always ceased about midday. He also complained of loss of weight and general malaise.

On examination the child was thin, but no other abnormal physical signs were detected. The early morning vomit was about 100 ml. of greenish-yellow, clear, glairy fluid. The temperature, pulse, and respiration rate remained normal throughout. The blood count, E.S.R., catheter urine, and a straight radiograph of the skull and chest were all normal. The cerebrospinal fluid was clear and colourless, under pressure of 80 mm. of water; no clotting occurred; cells 2 per 3 c.mm.; W.R. negative; Lange, no precipitation. The visiting ophthalmic surgeon, Mr. Eugene Wolff, declared the fundi to be normal, as did the neurologist, Dr. Hinds Howell, who also found no evidence of abnormal signs in the central nervous system.

Several attempts at a barium-meal examination were frustrated by vomiting, but eventually some was retained. The report stated: "Oesophagus, no obstruction; stomach, slight dilatation; duodenum, cap not clearly seen, no tenderness; caecum, no tenderness, mobile. Stomach surprisingly shows 26-hour delay and irregularity of the pyloric end." Pyloric obstruction of unknown aetiology was diagnosed, a surgical opinion was obtained, and laparotomy was advised.

On Sept. 13, as the child was showing signs of dehydration, an intravenous drip infusion of saline was set up in preparation for a laparotomy next day. While this was being done in the afternoon, the child complained of headache, and this was the first occasion on which the headache was noted to have persisted after midday. At 7 a.m. on the 14th, respiration became irregular, the face flushed, and the neck rigid and extended. Shortly afterwards the patient became cyanosed; the pupils were widely dilated and did not react to light; respiration became shallow and then imperceptible; the radial pulses were palpable, but heart sounds could still be faintly heard. Nikethamide and digoxin were given intravenously; and artificial respiration was started with oxygen administered by a B.L.B. mask. The heart beat improved at first but later became weaker and ceased at 9.15 a.m. The respiratory rhythm showed no signs of restoration.

At necropsy no anatomical defect of the pylorus could be found, and the stomach was not obviously dilated. A large gush of cerebrospinal fluid appeared when the tentorium cerebelli was cut, and a tumour was found in the cerebellum, about 2 in. (5 cm.) in diameter and approximately symmetrical about the midline. The morbid histological report stated that the tissue was "a spongioblastoma showing clear evidence of rapid growth."

#### COMMENT

The mechanism of the delay must presumably have been a gross interference with the normal peristaltic movements. The radiographic appearance of the stomach was not suggestive of gastroparesis, and it seems likely that there was a central interference with the normal vagal control of the stomach leading to a gastric stasis, such as was observed by Dragstedt and Schafer (1945) in three of their series of 15 cases in which vagotomy was performed for peptic ulcer. Orr and Johnson (1947) also found that most of their patients after vagal resection had a six-hour residue, and two had a 24-hour delay without any evidence of organic obstruction and without any inconvenience (Orr, personal communication).

My thanks are due to Dr. Bruce Williamson, physician in charge of the case, and to Mr. Roland Segar, medical superintendent of Wellhouse Hospital, for permission to publish the case.

H. R. MALLOWS, M.A., M.B.,  
Surgeon, Lieut., R.N.; Late House-Physician,  
Wellhouse Hospital.

## Reviews

### EXAMINING THE EYE

*Diagnostic Examination of the Eye. Step-by-Step Procedure.* By Conrad Berens, M.D., F.A.C.S., and Joshua Zuckerman, M.D., C.M., F.A.C.S. (Pp. 711; 410 illustrations, including 48 in full colour on 13 plates. £4 10s.) Philadelphia and London: J. B. Lippincott Company.

As the specialties in medicine become more and more differentiated, so the elaboration of their diagnostic techniques increases. In no branch of medicine is this more evident than in ophthalmology; and, though the standard techniques of focal illumination and ophthalmoscopy can fortunately provide a wealth of information for the practitioner, the eye is particularly suited to the development of specialized methods for minute objective examination because of its optical properties, while the high differentiation of the visual sense invites the elaboration of refinements in subjective tests. The extent to which this tendency has been carried in ophthalmology is seen in the fact that a book of 711 pages has been filled—without much “padding”—with descriptions of a multitude of such methods.

The book is arranged in “steps.” Step 1 is the interrogation of the patient and the interpretation of his complaints; step 2, a general survey of the patient and the gross ocular appearance; step 3, palpation of the globe and its adnexa; step 4, auscultation—useful in eliciting a bruit in arteriovenous aneurysm, and said to be helpful in detecting an orbital foreign body when an increased resonance to the patient’s speaking voice is heard through the stethoscope placed over the closed lids; step 5, visual acuity for distance and near (accommodation); step 6, motor anomalies—an elaborate chapter; step 7, confrontation fields; step 8, biomicroscopy with the slit-lamp; step 9, ophthalmoscopy; step 10, transillumination; step 11, contact illumination; step 12, retinoscopy and refraction; step 13, tonometry; step 14, post-cycloplegic tests; step 15, colour-vision testing; step 16, fusion; step 17, light sense; step 18, perimetry; step 19, general supplementary tests; step 20, the summary of clinical findings, how to give advice to the patient, etc. As if this were not enough, in a further 271 pages the authors describe supplementary examinations, including such techniques as gonioscopy, red-free ophthalmoscopy, angioscopy, eikonometry, and many others.

The book is interesting, well and profusely illustrated, and contains a wealth of information, but it illustrates the tendency for the elaboration of methods to go to the extreme of becoming an end in itself. For example, a complex apparatus involving a large and expensive optical cabinet seems hardly necessary to measure the inter-pupillary distance. And among all the modernity it is somewhat of a shock to find the pupillary pathways described after the scheme of Bernheimer, which has for some considerable time been shown to be wrong.

STEWART DUKE-ELDER.

### RADIANT ENERGY AND HEALTH

*Applications of Germicidal, Erythemat and Infra-red Energy.* By Matthew Luckiesh, D.Sc., D.E. (Pp. 463; illustrated. 30s.) New York: D. Van Nostrand Co., Inc. London: Macmillan and Co. 1946.

Dr. Luckiesh, director of the research laboratory of the General Electric Company, U.S.A., has written an authoritative book on the use of radiant energy for human welfare. It is fully illustrated with spectrograms and graphs showing the range of radiant energy in the infra-red, visible, and ultra-violet regions of the spectrum, and the reflection by and penetration of the skin by these different rays, whether coming from the sun and the light of the sky or from various artificial sources which the author describes and evaluates. He discusses fully the germicidal effectiveness of the recently developed sources of ultra-violet rays used for killing air-borne and water-borne (3) a. thus preventing the spread of infection in rooms and

The canination of food, and keeping the air in containers have been tungsten-filament lamp, with special glass for the uterus, with c

bulb which transmits ultra-violet rays, can be used, or low-pressure mercury-vapour lamps, the bulbs containing the small arcs being in similar glass. For production of fluorescent light the bulbs can be coated with phosphors on the inside surface, and by this means even a dark source of ultra-violet rays is obtainable.

The use of these lamps in air-ventilation ducts and on the ceilings of occupied rooms greatly diminishes the number of bacteria and, therefore, catarrhal and other infections. Plates illustrate the germicidal power by showing the result of bacterial growth in Petri dishes exposed to the air before and after irradiation. One illustration shows a work-room in which a “sun” lamp emits ultra-violet light of the wavelength of the midday summer sun. It is fixed in the ceiling and radiates a sufficient amount of erythemat energy. Such an installation has been used with benefit to health for 20 years. Young tomato plants are conservative indicators of that intensity of germicidal rays which it is safe for the eye and skin to be exposed to. A minimal perceptible erythemat effect is obtained in 20 minutes’ exposure to midday sun on a clear day in summer and in about three hours in mid-winter. Rays longer than those that cause most erythema tan the best.

The author describes exact methods of measuring radiant energy, and considers both the very effective ultra-violet rays and the infra-red and luminous rays, as well as their relative influence on welfare and their penetration of the skin. He exposes the quackery of so-called colour therapy, and proves the safety of new sources of illumination with some unfamiliar tints. He devotes a chapter to the fading of materials and another to the influence of radiant energy on plant life.

LEONARD HILL.

### HYPOGLYCAEMIC STATES

*L’Hyperinsulinie. Les Etats de Suractivité Fonctionnelle du Pancréas Endocrine en Médecine Expérimentale et en Clinique.* By Marcel Sendrail. (Pp. 256; 25 figures and 2 in colour. 500 francs.) Paris: Masson et Cie. 1947.

The author, professor of general pathology at Toulouse, has written a detailed survey of hypoglycaemic states, which he designates by a new term—“hyperinsulinie.” He discusses both experimental and clinical data and quotes or mentions most of the literature on this subject, confining his references much less exclusively to the work of his compatriots than do the authors of most French monographs. But the misspelling of foreign authors’ names is so frequent as to be annoying. The quotation of contrary findings and opinions and theoretical possibilities in juxtaposition confuses the reader, since the author often fails to express his own opinion on which view is right. It seems that he must mention everything and appraise little in this vast compendium. He considers every imaginable cause of hypoglycaemia—pancreatic insuloma, liver conditions, starvation, other endocrine disturbances, and a curious group of “renal” and “morphine” hypoglycaemias whose nature will be obscure to the reader.

A word or two on nomenclature: the author rejects the commonly used English term “hyperinsulinism”—a nasty hybrid, no doubt, but it has come to mean a hypoglycaemia produced by a pancreatic tumour and excessive uncontrolled insulin production. He does not use the accepted French “hyperinsulinémie” to denote an excess of insulin in circulation—presumed though never proved. He has invented the word “hyperinsulinie” as being more in the traditional French form. This it may be, but he uses it too vaguely and ascribes it not only to conditions that arise from insulomas but to hypoglycaemic states, “insulinaries rénales,” and others where excess of insulin is highly improbable. I have looked in vain for a definition of true hypoglycaemic levels in this book. Figures of 70 to 80 mg. of blood sugar per 100 ml. are constantly referred to in both the experimental and clinical section as indicating hypoglycaemia, yet such figures are within the accepted normal limits.

The author describes the experimental work done by himself and his colleagues at Toulouse. It has two main aspects. First, they have studied the effect of sympathetic influences on the pancreas by periarterial section of all pancreatic arteries, and the author claims that this causes hypoglycaemia “hyperinsulinie,” though the graphs do not show it very clearly.

Secondly, as a test of insulin sensitivity they use a new technique—the *intramuscular* injection of 20–30 units (0.5 unit/kg. body weight), which is said to cause a more regular depression of blood sugar than the usual intravenous test. The book would be very useful for study and reference if it had an index.

R. D. LAWRENCE.

### LABORATORY METHODS

*Clinica y Laboratorio.* By Dr. G. Pittaluga, in collaboration with E. Gajan and A. Guernica. (Pp. 459; illustrated. Paper covers: \$7.00; cloth \$9.00.) Habana: M. V. Fresneda, Neptuno 561. Cuba.

In this book on clinical practice and the laboratory the authors have critically considered laboratory techniques and methods of examination in order to demonstrate which are the most informative and accurate for clinical diagnosis. The only descriptions of laboratory methods given are of those tests devised by the authors themselves, and either little known or of which accounts have not hitherto been published, which they have found to give more accurate results or be less difficult to perform. They give references to all standard procedures, and at the end of each chapter a full and up-to-date bibliography.

Especially well written is the section on examination of the functional capacity of the kidney. The authors present a well-balanced account of the various kidney tests, including measurement of glomerular filtration rate, effective plasma flow, and maximal tubular capacity. The chapters on liver function and mycology are also excellent. The photomicrographs and illustrations are of a high standard. The book is well produced and should be of great use to the practising physician.

W. T. COOKE.

### SUICIDE

*Suicide and the Meaning of Life.* By Margarethe von Andics. Preface by Prof. Cyril Burt. (Pp. 219. 8s. 6d.) London: William Hodge and Co. 1947.

This book is based upon a study of 43 men and 57 women, 70% being unskilled workers, who had attempted suicide and were examined by Dr. von Andics at the psychiatric and neurological clinic at Vienna, where they were sent by the police commissioner of their respective districts. The author approached the material as a psychologist, and excluded from examination all cases of attempted suicide by the mentally deranged or by inebriates in a state of intoxication. Even so she was not primarily concerned with the unconscious genesis of the act, but with the experience itself as it affected the consciousness of the individual, and she noted, like other observers, the occasional cathartic effect of the attempt.

Dr. Andics believes that for 100 persons who decide to commit suicide there are about 250 motives. This neat ratio probably means no more than the fact that the motive here, as so often elsewhere in anti-social activity, is complex. Indeed, like other workers in this field, she finds that suicide and attempted suicide occur when several of life's difficulties intersect. She states that 81% of her patients had had an unfavourable childhood and a similar proportion had made no friends. Above a certain minimum standard it was not so much the smallness of income or the insufficiency of the livelihood that impelled the attempt but uncertainty and aimlessness about the future. The subjective reaction of the women was in marked contrast to the objective outlook of the men, who were mainly concerned with material issues and principles. It was found that subjective factors may leave ineffaceable traces in the person's character and sometimes operate in a future conflict. The interesting fact emerged that an overwhelming majority in both sexes were sexually subnormal, and that this was an indirect cause of attempted suicide and acted either by isolating the person or by making the attachment to one single partner irreplaceable if death or misadventure intervened.

The number of cases is too small for the author's conclusions on these and other topics in the book to be more than interesting, but some of the excerpts from her notes are illuminating and the book is clearly written. There is no indication of the date of the investigation, a matter to be regretted in view of the disturbed state of Europe in recent years.

W. NORWOOD EAST.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Social Health and Morals.* By I. Fraser Mackenzie, M.D., D.P.H., D.T.M.&H. (Pp. 173. 7s. 6d.) London: Victor Gollancz. 1947. Includes discussion of the sexual instinct in society, venereal disease, marriage and family life, trial marriage, and divorce.

*Malaria.* By W. K. Blackie, M.D., Ph.D., F.R.C.P.Ed., D.T.M.&H. (Pp. 101. 10s. 6d.) Capetown: The African Bookman (for the Post-Graduate Press). 1947.

A general account of malaria, with an introductory historical review and special reference to forms of the disease met with in Africa.

*Abnormal Psychology.* By J. D. Page. (Pp. 441. 5s. 4d. or £1.) New York and London: McGraw-Hill Book Company. 1947.

An introductory textbook of mental disorders, intended for students with some knowledge of psychology.

*Paediatrics for Nurses.* By A. G. Watkins, M.D., F.R.C.P. (Pp. 192. 10s.) Bristol: John Wright and Sons. London: Simpkin Marshall. 1947.

A clinical account of diseases of children, intended for nurses.

*The Conduct of Life Assurance Examinations.* By E. M. Brockbank, M.B.E., M.D.Vict., F.R.C.P. 2nd ed. (Pp. 176. 12s. 6d.) London: H. K. Lewis. 1947.

An account of how to examine persons for life assurance companies.

*The 1947 Year Book of Radiology.* Edited by C. A. Waters, M.D., and I. I. Kaplan, M.D., F.A.C.R. (Pp. 416. \$5.50 or 30s.) Chicago: The Year Book Publishers, Inc. 1947.

Recent advances in radiological diagnosis and therapeutics; with many illustrations.

*Die Diagnostik und Therapie des Nebennierenausfalls und das Krankheitsbild der relativen Nebennierenrindensuffizienz (Hypoadrenie).* By A. Kappert. (Pp. 102. 8 Swiss francs.) Basle: Benno Schwabe and Co. 1947.

A monograph on the diagnosis and treatment of adrenal cortical insufficiency.

*Clinical Methods in Surgery.* By K. Das, M.B., F.R.C.S. (Pp. 240. Rs.20 or 35s.) Calcutta: The City Book Company. 1947.

Describes the clinical examination of surgical cases.

*The Story of a Scottish Voluntary Hospital.* By T. C. Mackenzie, M.D., F.R.C.P.Ed. (Pp. 284. 8s. 6d.) Inverness: "Northern Chronicle" Office. 1946.

A history of the Royal Northern Infirmary, Inverness.

*A Manual of Fractures and Dislocations.* By B. B. Stimson, A.B., M.D., Med.Sc.D., F.A.C.S. 2nd ed. (Pp. 223. 17s.) London: Henry Kimpton. 1947.

A short guide intended for medical students.

*Health Services in England.* By R. C. Wofinden, M.D., B.S., D.P.H., D.P.A. (Pp. 191. 10s.) Bristol: John Wright and Sons. London: Simpkin Marshall (1941), Ltd. 1947.

A survey of public health services in England.

*The Causation and Treatment of Delayed Union in Fractures of the Long Bone.* By K. W. Starr, O.B.E., M.S., F.R.C.S., F.A.C.S., F.R.A.C.S. (Pp. 233. 42s.) London: Butterworth and Co., Ltd. 1947.

An essay awarded the Jacksonian Prize in 1944.

*Handbook of Communicable Diseases.* By F. H. Top, A.B., M.D., M.P.H., F.A.C.P., et al. 2nd ed. (Pp. 992. 42s.) London: Henry Kimpton. 1947.

An illustrated textbook of communicable diseases; with references.

*The Selected Writings of Benjamin Rush.* Edited by D. D. Runes. (Pp. 433. 55s.) New York: Philosophical Library, Inc. 1947.

Dr. Rush's liberal ideas were later of great influence during the American Revolution.

*Physical Medicine in General Practice.* Edited by A. L. Watkins, M.D. (Pp. 341. 30s.) London: J. B. Lippincott Company. 1946.

A practical account for the general practitioner.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 20 1947

## THE MINISTER'S REFUSAL

About a year ago the British Medical Association sought by means of a plebiscite the opinion of the medical profession on the National Health Service Act. The result of the plebiscite showed that for all categories voting there was a majority against negotiations on Regulations within the framework of the Act. Of the general practitioners voting the percentage of Noes was 64. When the Council of the B.M.A. met on Dec. 11, 1946, to decide what action to take on the results of the plebiscite it passed this Resolution to be forwarded to a special meeting of the Representative Body:

That the Negotiating Committee be advised that in view of the results of the plebiscite the Minister be informed that, because of the divergence between the principles of the profession and the provisions of the National Health Service Act, the Committee is unable to enter into discussions with the Minister on the Regulations to be made under that Act.

On Jan. 2 of this year the three Presidents of the Royal College of Physicians, the Royal College of Surgeons, and the Royal College of Obstetricians and Gynaecologists wrote a letter to Mr. Bevan<sup>1</sup> in which they sought to avoid the impasse that would arise if the medical profession refused to renew discussions with the Government on the National Health Service Act. Mr. Bevan replied<sup>1</sup> that if discussions took place he would "endeavour to meet any views of the profession which do not conflict with the principles of the Act." When the Representative Body met on Jan. 28 of this year it passed the following Resolution:

That the Association, having considered the final results of the plebiscite and the Minister's letter of Jan. 6 to the Presidents of the Royal Colleges, and desiring to secure for the people the best possible Health Service, is willing that discussions be entered into with the Minister to that end, provided that such discussions are comprehensive in their scope and that the possibility that they may lead to further legislation is not excluded; that after the conclusion of these discussions a second plebiscite of the profession be taken on the issue of entering the Service.

On Jan. 31 the Minister expressed his willingness to resume discussions with the Negotiating Committee in the light of the above Resolution. Since that date the Negotiating Committee has been hard at work, and the six subcommittees it set up have had many meetings both at B.M.A. House and with the officers of the Ministry of Health. These discussions have been "comprehensive in scope" and have been conducted on the assurance that the possibility of amendment would not be excluded. By now all members of the profession in Britain will have received copies of the statement of the Negotiating Committee summarizing the work of the past months and put before the Minister in advance of the meeting with him on Dec. 2 and 3. The Minister's reply has also been circu-

lated, and both documents are printed in this week's *Supplement*, together with the legal opinion of Sir Cyril Radcliffe, K.C., and Mr. J. H. Stamp on the interpretation of Section 35 of the Act.

Commenting on the situation in the first week of this year *The Times* said in a leading article<sup>2</sup>: "Yet a crisis of confidence has been precipitated, and it cannot be denied that Mr. Bevan himself has helped to precipitate it." We expressed the hope then<sup>3</sup> that Mr. Bevan would "seize the opportunity to show himself a statesman by responding to the profession's earnest desire to discuss clauses of the Act as well as the Regulations." Mr. Bevan has certainly discussed clauses of the Act, but in spite of the cogent case put to him by the Negotiating Committee he has refused to amend the Act in any one particular and has in effect done little to remove those grave doubts on certain aspects of the Act which unsettle the majority of the profession in this country. He has made, it is true, concessions to the consultants and specialists, in particular by his offer to set aside in State hospitals a limited number of beds in which consultants and specialists may treat patients with no restriction on the fees to be charged. Mr. Bevan, whose persuasively written reply is much more conciliatory in tone than his oral responses of Dec. 2 and 3, has gone some way to ease difficulties of procedure, but the substance of the Act is unchanged. Has he precipitated another crisis of confidence by refusing to amend the Act in a way that would remove the doubts of those who see it as the first step to a whole-time State medical service?

The Negotiating Committee's statement is long, and so is the Minister's reply to it. The legal opinion on Section 35 presents some difficulty to those not accustomed to following legal arguments. It is hoped, however, that medical men and women will find the time to read and reread these important statements so that they will fully understand the issues when the time comes to answer the questions in the plebiscite to be issued on Jan. 31. There is the danger that many will become confused by the details of the arguments, and that some who flatter themselves as practical men will look only at the financial implications of service under the Act. Yet the essence of the Negotiating Committee's case is nothing more nor less than the preservation of the essential freedoms of a profession with centuries of a fine tradition behind it. At a public luncheon the other week Mr. Herbert Morrison boasted of the revolution now taking place in Britain. Mr. Bevan's National Health Service Act is part of this revolution. His proposed State monopoly of hospitals and his proposed purchase of the ownership of private practices are two important measures directed to the eventual establishment of a whole-time salaried State medical service. The consultant or specialist who perforce must work in the State hospital will while he works in it be an employee of the State through the Regional Board. The general practitioner in the new Health Service will be a servant of the State through the Executive Councils. Medical men have always been proud to serve the community in which they

live. This tradition of direct service to the patient is now in the process of being broken. The doctor will now serve the patient through the State. The medical profession will come under the dominance of a vast administrative machine operated by one man—the Minister of Health—exercising a power never before wielded by any one man in the history of medicine. Under the new Act, which the Minister refuses to amend in spite of the reasoned case of the Negotiating Committee, all medical men taking service in hospital as well as in general practice will cease to have an undivided allegiance to the individual patient. The doctor will have a duty not only to the patient but to the paymaster, and the paymaster himself will have one eye on the political weather and the other on his master, the Treasury. Apart from any detailed consideration of this, that, or the other section of the Act, or this, that, or the other method of payment, it is undeniable that the National Health Service Act is a revolutionary measure introduced into a sphere of public life in which the trial-and-error of evolutionary development has increased knowledge and has raised British medicine into the proud position it now holds in the esteem of the world. "Evolution, not Revolution," was indeed the title of an article published in the *Supplement*<sup>1</sup> by the late Dr. G. C. Anderson. It is the way of progress most suited to the profession of medicine and most congenial at least to the English temperament. But Mr. Bevan will have none of this and seeks to impose what to the majority of medical men is unacceptable.

In paragraph 3 of its document the Negotiating Committee at the outset asked the Minister "to seek by amendment of the Act where necessary to have the changes made to meet the points raised by the Committee." The Negotiating Committee, it is well to point out, is representative of all phases of professional life. In addition to the British Medical Association there are represented on it the Royal College of Physicians, the Royal College of Surgeons, the Royal College of Obstetricians and Gynaecologists, the Scottish Royal Corporations, the Society of Apothecaries, the Society of Medical Officers of Health, the Medical Women's Federation, and representatives of the Non-teaching Voluntary Hospital Staffs. Jointly these bodies have failed to secure the essential amendments asked for. Jointly, it is hoped, they will persist in seeking those changes if the profession by plebiscite asks them to do so. The chief points which the Negotiating Committee wish to secure, if necessary by amendment, are listed in the summary at the end of the Committee's document. The Committee has agreed with the principle that the Service should be available to the whole community, with the proposed hospital planning and development on regional lines, and with the general structure of Local Executive Councils. The Committee considered it to be undesirable that a Minister should be empowered to establish a monopoly of hospitals, and requested that private nursing-homes should be excluded from the definition of hospitals and clinics set out in Sections 9 and 10 of the Act. They asked, too, that the Minister's discretion should be replaced by an obligation to permit specialists in the Service to attend their patients in private hospital accommodation. The Minister has now promised to arrange in the Hospital Service for four types of beds: (1) beds for patients to be

treated free of charge; (2) beds for patients who wish to pay for privacy but not for consultant fees; (3) beds for patients who wish to obtain privacy and also wish to pay private fees according to a Ministerial scale; (4) beds in which no limitation on fees is imposed. The Minister also has given his assurance that private nursing-homes run for profit will not be taken over by the State. These concessions can in time be as easily withdrawn as given, and the present Minister's assurances are in any case not binding on any future Minister. After no great lapse of time the young consultant of to-day will find himself working as a whole-time servant of the State in a State hospital.

Mr. Bevan has refused to remove the anxieties of general practitioners by amending the Act. He refuses to alter the mechanism of distribution, and the power to direct doctors remains in the Act. He refuses to grant the right of appeal to the High Court on a decision to remove a practitioner's name from the list of an Executive Council. He refuses to meet the profession's strongly rooted objection to a basic salary. Even though almost the only argument he himself used in supporting a basic salary was that it was desirable for a young man entering general practice, he has made it applicable to all practitioners of whatever age entering the public service. General practitioners will naturally ask themselves to what is this salary *basic*, and the answer would appear to be that it is basic to a future whole-time salary. Mr. Bevan refuses to amend the Act in respect of the ownership of goodwill. The retention of the custom of buying and selling practices, which general practitioners as a whole regard as essential to their freedom as individual doctors, would be the one obstacle in the way of Mr. Bevan's intention to direct them by the mechanism of the Medical Practices Committee.

In addition to all this Mr. Bevan refuses to remove the ambiguity and anomalies of Section 35 of the Act in spite of the fact that his interpretation of the wording in particular of Subsection 4 of this section is challenged by two of the most prominent legal advisers in this country, Sir Cyril Radcliffe, K.C., and Mr. J. H. Stamp, the latter being counsel to the Treasury. Their reasons for disagreeing with the Minister's interpretation of Subsection 4 of Section 35 of the Act are set out in this week's *Supplement*. Their important conclusion is as follows:—

"If Sections 35 and 36 are allowed to become operative without amendment the profession and the Ministry alike will labour under embarrassing uncertainty on matters of great importance until the debatable matters have been finally adjudicated upon, and in the meantime steps may have been taken on the footing of a construction which is ultimately found erroneous with unfortunate consequences to all concerned. In our opinion it would involve a real hardship to the practitioners concerned if they were required to submit to such uncertainty when it has been clearly foreseen and can be removed by an amending Act."

Whether the Minister's interpretation is right or wrong, the interpretation of this subsection is so ambiguous that no general practitioner at present in partnership taking service under the Act will know where he stands in relation to partnership agreements entered into before the appointed

date—July 5, 1948. No one in fact will know what the subsection means until the matter has been settled in the Courts, and the Minister is content to leave it for the Courts to decide. In the meanwhile he gives his assurance that his interpretation is as stated in the Negotiating Committee's document, and on the basis of this proposed methods whereby those in the Service should not suffer financial loss owing to partnership agreements. But the sole concern of the Courts when called upon to interpret Section 35 will be with the wording of the Act and not with the assurances of Mr. Bevan or any subsequent Minister. Mr. Bevan could have remedied this situation by amending Section 35 so as to remove all ambiguity from it. This he refuses to do.

According to the Minister's interpretation of Subsection 4 of Section 35 (which with Section 36 on Compensation is reproduced in full in the *Supplement*) the Act does not determine partnership agreements entered into before the appointed day. This means that two doctors in partnership with agreement to buy or sell a share of the practice on the death or retirement of one or other partner can hold each other to this agreement if one or both enter the National Health Service in July of next year. The sale of a share under pre-existing partnership agreements will not constitute an offence under Section 35 (2) of the Act. There are not a few partnerships in which the one partner conducts the private side of the practice and the other the panel side. The Minister has stated that he does not wish to interfere with private practice. Many men, even though the Act might be rendered acceptable, would still wish to continue in private practice, and it is likely that in such a partnership as is described the one partner will continue in private practice and the other will place his name on the list of the Local Executive Council. The matter is summarized thus by the Negotiating Committee:

"In fulfilling his contractual obligations under a partnership deed a practitioner may be required (a) to buy a partner's public practice, the capital value of which he cannot realize, the income from which he cannot receive, and compensation for which is not available to him. . . ."

The effect of the Minister's interpretation is to force the private practitioner into the public service.

The Minister, having introduced a basic salary against the wishes of the profession, has settled upon a method of capitation payment which again leaves the actual financial position somewhat obscure. The capitation fee, for example, will vary from area to area according to the number of doctors taking part in the Service. The Minister proposes that there should be created a central pool of £40,826,250. This sum is arrived at by multiplying 95% of the estimated population of Great Britain for June, 1948, by 18s. From this pool is to be subtracted £6,000,000 odd to provide mileage fees, basic salary, and fees for certain special services. If, in fact, 95% of the population were on doctors' lists, and 17,900 principals joined the Service, the actual remuneration per head would amount to 17s. 6d. There will in addition be maternity fees, fees for emergencies and anaesthetics, and special grants for training assistants. There will also be set aside a sum equal to 1% of the central fund for "inducement" payments to assist doctors to practise in difficult areas.

Preoccupation with financial and other details, important as they are, for medical men have their living to make, must not obscure the main issue which the medical profession now has to face. This issue is summed up in the first of the principles enunciated by the Negotiating Committee exactly two years ago, thus:

"The medical profession is, in the public interest, opposed to any form of service which leads directly or indirectly to the profession as a whole becoming full-time salaried servants of the State or local authorities."

Mr. Bevan claims that his Act does not conflict with any of the profession's principles. We believe, on the contrary, that the Act is the first step towards a whole-time salaried State medical service, and the refusal of Mr. Bevan to amend the Act strengthens this belief. If the medical profession after careful reflection on the effect of the Act as a whole comes to the same conclusion, then it must decide for itself whether the above principle is merely a form of words or something which it considers fundamental to the practice of the art and science of medicine.

## SUICIDE IN PEACE AND WAR

The recently published *Criminal Statistics* for the year 1939-45 show that the number of suicides and attempted suicides in England and Wales decreased during the war. In 1938 there were 5,263 suicides, and the number diminished almost regularly until 1944, when the total was 3,651. There was a slight rise to 3,818 in 1945. The number of men who committed suicide each year, 1938 to 1945 inclusive, was almost twice the number of women—22,618 males and 11,646 females. In both sexes the numbers increased in each decade, and reached a maximum in people aged 40 and over. In those aged 21 to 30 years, 2,113 males and 942 females committed suicide; for 50 to 60 years the figures were 4,812 males and 2,822 females; and, for 60 and over, 7,957 males and 3,256 females. These figures support the general view that men are more prone to commit suicide than women and that the tendency increases with age. F. L. Hoffman,<sup>1</sup> as the result of thirty-five years' experience in insurance cases, considers that the age factor in suicide is of most importance among the very young and the very old. Karl G. Dahlgren,<sup>2</sup> in a recent and comprehensive psychiatric and statistical investigation in Sweden found that, broadly speaking, the increase with advancing years of the number of suicides in relation to the size of the population groups still holds good; he refers to the work of Füllkrug<sup>3</sup> for Germany from 1919 to 1923, of Dublin and Bunzel<sup>4</sup> for the U.S.A. from 1911 to 1930 (insurance cases) and of Wicksell<sup>5</sup> for Sweden from 1921 to 1929. Dahlgren points out that the curve of the suicide incidence in Germany shows a small peak for both men and women aged 20 to 25 years. A similar peak is faintly shown in Wicksell's curve for Swedish women aged 30 to 35 years.

<sup>10</sup> Article in *Encyclopaedia Britannica Book of the Year*, 1945. Chicago.

<sup>11</sup> *Munch. med. Wschr.*, 1906, 53, 1408.

De Jastrzebski<sup>6</sup> collected figures showing the suicide rate per million in nine belligerent countries and non-belligerent Sweden and Switzerland in the years immediately before, during, and after the first world war. In each instance a notable decline occurred during the war. This writer points out that the men withdrawn from civil life, and consequently from the populations under statistical review, were not at the ages when suicide is most prevalent. He considers that, had suicide remained at the same level among the civil population as previously, the general rate would have risen owing to there being fewer people left at ages when suicide is less likely. He believes his figures show that mental strain is not one of the prime causes of suicide, but that lack of interest in life itself is one if not the most potent factor. However this may be, the fact that the percentage decline in 1915 to 1918 was greatest in Sweden and greater in Switzerland than in six of the belligerent countries suggests a complex motivation. It could hardly be otherwise, for the related emotional disturbance, whether psychotic or non-psychotic, is in the final analysis itself complex. Moreover, the view formerly held by some that suicide was inevitably due to mental disease is no longer acceptable. Henderson and Gillespie<sup>7</sup> have been impressed by the large proportion of cases of attempted suicide admitted to the Royal Infirmary, Edinburgh, and Guy's Hospital, London, that have never previously seemed to require psychiatric guidance or control; and Norwood East,<sup>8</sup> in an analysis of 1,000 consecutive cases of attempted suicide, estimated that about one-fifth were certifiable as insane.

The number of attempted suicides recorded in the *Criminal Statistics* for the year 1938 was 3,303. This is an underestimate, since all cases are not reported to the police. The figure reached a minimum of 2,386 in 1942; it rose to 2,600 in 1943, and a further rise to 2,972 was recorded in 1945. During the years 1938 to 1945 inclusive 11,711 males and 10,248 females attempted suicide. The number recorded was greatest among those aged 30 to 40 years; those aged 60 and over provided the next highest number. The greatest number of males attempting suicide was among those who were 60 and over and was 2,836, while the corresponding number for females was among those aged 30 to 40 and was 2,231. The second highest incidence for males occurred in this group. Dahlgren states that most authors find the largest number of cases of attempted suicide among men in those aged 25 to 29 years, and among women in those aged 20 to 24. He refers to Piker,<sup>9</sup> who found the figure for men was highest in those aged 25 to 29 years and for women in those aged 15 to 29 years. East found that in males the greatest incidence was in the group 25 to 30 years. Former volumes of *Criminal Statistics* show that during the years 1921 to 1938 there was an almost constant rise in the number of suicides and attempted suicides in England and Wales. The figures for the years after the second world war may have unusual social significance.

The seasonal incidence of suicide and attempted suicide is not considered in the *Criminal Statistics* but has some general interest. Esquirol found that suicides were most numerous in spring and summer. Morselli arranged the seasons by greatest incidence of suicide in the order summer, spring, autumn, and winter. Hoffman stated that

the mortality rate per 100,000 in 27 American cities (1924 to 1926) was highest in December and lowest in August. Lotka<sup>10</sup> found that during 1940 in the U.S.A. the peak month was April with a suicide rate of 16.2 per 100,000. The low points were 12.5 in January and 12.9 in November. Dahlgren states that in most European countries the peak of the curve is reached in May or June. For attempted suicide Dahlgren refers to the work of Rothfuchs<sup>11</sup> and East among others. The former found a maximum in June to July, a smaller peak of incidence in September, and a minimum in March. East found in his cases a maximum in June to July and a minimum in February. Dahlgren noted that the figures for both sexes were often highest in April, with a less pronounced increase in November for men and in October for women. He found a distinct periodicity of attempted suicide in both psychotic and non-psychotic subjects. Various reasons have been suggested for the seasonal incidence, yet none are very convincing. It is not without reason that suicide has been described as our most baffling social disease.

#### ADVANCE INFORMATION

The British Medical Association agreed with the Ministry of Health that the Negotiating Committee's statement should be issued at the same time as the Minister's reply to it. It was agreed that no information should be divulged which would prejudice in advance the issue between the B.M.A. and the Minister of Health. On its side the B.M.A. has kept faith. It was therefore disturbing to find in the *Tribune* on Friday, Dec. 12, two long paragraphs under the title of "What's Happening" which could have been written only by someone with direct knowledge of the confidential discussions between the Minister and the Negotiating Committee on Dec. 2 and 3.

The *Tribune* writes: "At his final meetings with the Negotiating Committee, Aneurin Bevan made it quite clear that the Service will start on July 5 'with the resources at our disposal'." The words "with the resources at our disposal" appear between quotation marks. As there has been no published account of the discussions with the Minister on Dec. 2 and 3 it is pertinent to ask whom or what the *Tribune* is quoting. This paper goes on to state that Mr. Bevan "stood firm" on the question of buying and selling of practices, the distribution of doctors, and basic salary. It then suggests that the consultants and specialists "are likely to break away." The *Tribune* is obviously supporting Mr. Bevan's evident intention to divide the profession.

The *Tribune* makes a remarkable disclosure of financial details which could have been worked out only by someone in full possession of the figures given by Mr. Bevan to the Negotiating Committee on Dec. 2 and 3. Thus "the capitation fee will work out, it is stated, at not less than 17s. 6d. per head of the population. . . ." Again we may ask who made this statement.

"Politically," the *Tribune* states, "the Minister's firmness has been most important. If he had been weak in face of this reactionary profession . . . it would have increased doubts as to the intention to carry out a Socialist programme."

Can we take this as a confirmation of the suspicion many have that in refusing to amend the Act the Minister is governed chiefly by political considerations?

## MUSCULAR CONTRACTION

With the basic mechanism of muscular contraction still unknown, there is a special value in the collection of detailed and precise data on the observable effects which accompany contraction. The simplest of these is the release of heat which Prof. A. V. Hill has long studied at University College under the inevitably confused conditions of continued stimulation. Valuable as these earlier investigations have been, it is clearly more illuminating as a test of theory to follow a single twitch of muscle through the successive stages of contraction, relaxation, and recovery. This he has now done, and his methods and results were described in a recent paper before the Royal Society.

His measurements were made on the leg muscle of frog at a temperature of zero Centigrade, but have been accompanied by sufficient comparison with more usual conditions to show that the heat changes thus observed can be accepted as typical. Under these conditions contraction lasts about 0.4 second, relaxation 0.6 second, and recovery is extended over some 45 minutes. Even so, however, the sorting out of the initial stages involves time measurements to an accuracy of two-thousandths of a second. Also, the total temperature rise resulting from a single twitch is no more than about  $0.0025^{\circ}\text{C}$ , so that for detailed analysis temperature measurements of the order of one-hundred-thousandth of a degree are needed. The difficulty, which he has surmounted, is to combine these two requirements of speed and sensitivity.

Procedure on the physical side was to translate the temperature changes to be recorded into changes of electric potential through a miniature thermopile of thickness comparable with the length of a red blood cell. This in itself gives a fair indication of the instrumental difficulties which are involved. The output from this thermopile was then fed into a spring-mounted mirror galvanometer designed and built to combine stability and speed of response. Final display was on the now familiar cathode-ray tube. By this time voltage had been multiplied by a factor of thirty million, and the deflection of the electron beam of the cathode-ray tube was equivalent to that which would have been obtained by observing the light beam of the mirror galvanometer from a distance of some 300 yards down the road. Any further magnification would have brought Prof. Hill to the stage when disturbance would have been introduced by the random movements of the atoms which make up the deflecting coil of the galvanometer. It may be said, therefore, that in a literal and exact sense sensitivity of measurement has been carried to the extreme limit possible.

The conclusions which follow are that to within two-thousandths of a second the release of heat and physical contraction begin simultaneously; that the release of heat begins at once at maximum rate as if the muscle had been "triggered" into activity; and that at no stage in the complete cycle represented by twitch and recovery is there any sign of a chemical reaction accompanied by the absorption of heat such as the theories of Szent-Györgyi would presuppose. Finally, there is the peculiarity, which like so much else is left for later explanation, that the initial release of heat in a single twitch is independent of the work done in contraction. It would be a very odd sort of cartridge, as Prof. Hill has pointed out, of which the same were true in the firing of a bullet. No wider picture is yet possible, facts have at least been provided which any future theory of muscular activity must either explain or be rejected.

WORLD FEDERATION OF ASSOCIATIONS OF  
CLINICAL PATHOLOGY

An international association of societies devoted to that branch of medicine known in this country and the United States as clinical pathology was brought into being at meetings held in Paris on Nov. 21 and 22, in the course of the first International Congress of the Société Française de Biologie Clinique. The International Conference had been called under the presidency of Prof. Polonovski, of the Paris Faculty of Medicine, but at its opening Prof. Polonovski, in recognition of the pioneer work of the European Association of Clinical Pathologists, invited its president, Dr. S. C. Dyke, of Wolverhampton, England, to occupy the chair. Delegates and observers attended from Belgium, Czechoslovakia, Denmark, France, Great Britain, Greece, Italy, Peru, and the United States.

The term "clinical pathology," though long accepted in both Great Britain and the United States, is not in general use in many Continental countries; the Conference therefore decided to adopt for international usage the term "clinical biology," defined by the European Association of Clinical Pathologists as "the application of pathology and all its related sciences to clinical medicine." The objects of the International Association were laid down as the establishment of permanent co-operation between the member national societies of clinical biology; the co-ordination of their scientific and technical methods; and the furtherance of clinical biology in every aspect by means of conferences, congresses, and meetings, and by the interchange of publications and more especially of personnel.

The Conference had before it texts of proposed statutes prepared both by the Société Française de Biologie Clinique and by the European Association of Clinical Pathologists. Though prepared independently, they showed a surprising degree of conformity, and in the course of two sessions the Conference was able to draw up a provisional constitution. This was designed according to the rules established by Unesco for its associated international bodies and sets up the governing body of the International Federation as a council or commission of the delegates from the national member societies. This council acts through the executive committee of six members elected by itself.

The English and French texts of the statutes will come up for ratification at a full meeting of the council which it is hoped to hold in England in the course of the next summer gathering of the British Association of Clinical Pathologists. The Conference elected its officers as follows: president, Dr. S. C. Dyke (England); secretaries, Dr. A. Durupt (France) and Dr. J. Ungar (England); vice-president, Prof. Raoul Kourilski (France); treasurer, Dr. W. H. McMenemey (England). The second office of vice-president was left vacant in the hope that it might be filled by a representative of the United States of America.

National societies devoted to clinical biology wishing to become members of the International Association are invited to communicate with either of the secretaries, Dr. A. Durupt, 20, Rue de la Pompe, Paris, or Dr. J. Ungar, Glaxo Laboratories, Greenford, Middlesex, England.

The work of rebuilding the King George V Merchant Seamen's Memorial Hospital in Malta, which was destroyed by the enemy in 1942, is now nearly complete. £15,000 is urgently needed for medical and surgical equipment. Donations, which will be gratefully acknowledged, should be sent to the Medical Secretary, 46, Denison House, Vauxhall Bridge Road, London, S.W.1.

## Fatal Cases of Influenza

SIR,—In connexion with the proposed investigation of fatal cases of influenza referred to in the paper on p. 994 of this issue of the *Journal*, I would like to invite the co-operation of practitioners. Would any practitioner who is interested in the subject and who might in the future be able to supply clinical details of fatal illnesses notified by him as being due to influenza please write to me at the address given below.—I am, etc.,

University Department of Medicine,  
The Royal Hospital, Sheffield, 1.

C. H. STUART-HARRIS.

## Erythroblastosis Foetalis and Breast-feeding

SIR,—The paper by Dr. I. A. B. Cathie (Oct. 25, p. 650) has given guidance of the clinical management of erythroblastosis foetalis. His conclusions confirm the suggestions concerning the breast-feeding of affected infants made by one of us some months ago.<sup>1</sup> However, a point of technique needs clarification.

Cathie incubated equal volumes of gastric secretion and serum of high Rh-antibody content for one hour and proceeded to investigate the resulting mixture for Rh antibodies. A similar experiment was carried out in the laboratories of the N.B.T.S., Sheffield, in August, 1946, by one of us (I. D.). The fasting gastric contents of six babies, all less than 10 days old, were used. The procedure adopted was identical with Cathie's, but it was found on testing the resultant mixture for antibody content, using known Rh-positive cells, that the mixture had a lytic action, and no results were obtainable. The pH of the mixture was determined with the facilities available and found to be acid. Attempts were made to neutralize this mixture, without satisfactory results. The acid nature of the gastric contents was expected.<sup>2,3</sup>

From the experiments conducted two further points of interest were observed. First, by separating the milk into lipid and aqueous fractions there was strong evidence to suggest that the antibody content was in the aqueous portion and not the lipid fraction. This was considered to be of importance in view of the possibility of antibody being ingested adsorbed on to fat molecules without digestion occurring. Secondly, it was found that by digesting breast milk containing Rh antibodies with rennin there was a definite reduction in antibody content of the milk examined. Rennin has been found in the stomach of infants during the first day of life,<sup>4</sup> and it is generally accepted that the digestive enzymes are present in the foetus some weeks before term.<sup>5</sup>

Further studies of the digestion of breast milk and antibodies are being undertaken as and when material and apparatus become available.—We are, etc.,

C. CHRISTOPHER BOWLEY.  
IVOR DUNSFORD.

Sheffield.

## Direction of Labour

SIR,—As a result of labour direction during the war the members of our profession have become used to certifying men as physically fit or unfit for specific jobs. On the whole such certification was in the interest of the worker, as it was a safeguard against men being compelled to do work at which they would be inefficient or which would be detrimental to their health. Obviously there was no ethical objection to such certification. But the recent introduction by the Government of the Control of Engagement Order may well raise an issue of ethical importance to the profession. For the first time in the history of our country legislation has been introduced to compel workers in peacetime to engage in work which is not their own choice. Without going into the arguments for and against this type of legislation, there can be little doubt that the vast majority of us look upon the Order as the introduction of industrial slavery. In the controversy which recently raged round the

proposed National Health Service our profession took a very strong line against the direction of doctors to take up practice in districts which were not their own choice. We took this stand on ethical grounds. The practice of compulsion, to which we rightly objected, is now being applied to the vast majority of citizens with very few exceptions.

Now here is the practical point. If the workers should prove recalcitrant it may well be that the Ministry of Labour will ask us to examine the rebels as to their fitness for the job to which they have been directed. If we agree to undertake such examinations we will make ourselves accessories to the enforcement of a practice which we consider morally wrong. On the other hand, if the worker should ask us in confidence for such an examination, there would be no ethical objection to issuing a certificate. The worker could use it or not as he saw fit. I trust the Association will give this matter immediate consideration and that it will warn members of the impropriety of conducting such examinations if asked to do so.—I am, etc.,

Woodford Green, Essex.

L. P. GRAY.

## B.C.G. Vaccination in Control of Tuberculosis

SIR,—I should be grateful if you would let me correct an error that has been pointed out to me in Table IV of my paper on B.C.G. vaccination (Nov. 29, p. 855). In the text of their paper Aronson and Palmer have grouped their non-pulmonary with their advanced pulmonary cases, and in the corresponding table they have failed to indicate that their advanced cases refer to pulmonary cases alone. On re-examination of their figures, it seems probable that the real numbers were as follows:—No. developing N.P.T.: 3 in vaccinated, 19 in control group; No. developing P.T.: 14 in vaccinated, 49 in control group. Though this change in distribution affects the N.P.T./P.T. ratio and the argument I have based on it, it does not, of course, alter the total number of cases in the vaccinated and control groups. Readers may be interested in a recent paper by Levine<sup>1</sup> in which he draws attention to technical defects in some of the American investigations on B.C.G. and to the completely negative results obtained by Blanch, Blanch, and Lieutier<sup>2</sup> in a study of over 100,000 infants vaccinated by B.C.G. in Uruguay.—I am, etc.,

G. S. WILSON.

## REFERENCES

SIR,—All tuberculosis workers in the field will welcome the pungent paper by Prof. G. S. Wilson on "The Value of B.C.G. Vaccination in Control of Tuberculosis" (Nov. 29, p. 855). I hope it will be read and re-read. He suggests a possible trial on nurses entering the larger hospitals. Too many would be lost sight of to make the trial a success. There are at present no short cuts for the eradication of pulmonary tuberculosis. Find, isolate, educate, treat, rehabilitate the adult positive case; encourage the sure but unspectacular work of tuberculosis health visitors. This, I suggest, is the hard but only way.—I am, etc.,

Church Stretton, Salop.

G. LISSANT COX.

SIR,—The critical article on B.C.G. by Prof. G. S. Wilson (Nov. 29, p. 856) and your able leading article thereon (p. 873) are of great interest at the present time. I propose to comment briefly on only one aspect of Prof. Wilson's paper—namely, his suggestion that, as children of tuberculous parents undergoing B.C.G. vaccination must be separated from their homes for 2 or 3 months following vaccination, this separation might be prolonged "till the tuberculous member of the family has been cured, has died, or has been admitted to an institution for chronic cases."

Dealing with each of these alternatives in order: (1) No patient can by definition be considered as "cured" until a minimum of five years from the onset of the disease, and many patients may take longer than this. I have, for instance, at present an afebrile patient aged 39 in this hospital who first showed a "positive" sputum 19 years ago. (2) The average survival time of a patient dying of pulmonary tuberculosis from the date of diagnosis is probably also in the neighbourhood of five years. (3) Where are the institutions for chronic cases at the present moment? Beds in them, in my experience, are practically unobtainable.

It seems obvious, therefore, that if these suggestions were acted on semi-permanent banishment of the child from its home environment would be necessitated, and I cannot feel that this disruption of family life would be approved of either on humanitarian grounds or by child psychiatrists even if practicable. I was glad to read in your leading article that tuberculin-negative nurses certainly need protection, a point I endeavoured to make in your correspondence columns some three years ago. Unfortunately, some of our leading tuberculosis workers still await conversion to this belief.—I am, etc.,

London, N.W.9.

W. E. SNELL.

### Student Health and the B.M.S.A.

SIR,—As a medical student who happens to have begun his studies a decade later than the majority I was greatly interested by the letter of Dr. G. H. Blair (Dec. 6, p. 931) on the B.M.S.A.'s proposal to make it compulsory for students to be medically examined. Your correspondent implies, in my opinion correctly, that this is an example of the political orientation which tilts the views of the organization, but I should like to discuss the probable aetiology of this "revolutionary" bias. Most students being in their adolescent or early adult phase of life, it seems not unexpected that a high proportion of them should be susceptible to impulsive social feelings. At this age, when the rational faculties tend to be submerged by the emotions, one would surely anticipate that impatience with prosaic conventionalism found its outlet in a sincere but quite misguided appetite for revolt. Unhappily, more experienced advocates of political extremism (whether to the "left" or to the "right") exploit and manipulate this common leaning.

I certainly recall going through this phase myself many years ago, but in my contact with students I have seen little sign of it among those who have reached the clinical stage of the curriculum. I did, however, encounter much of it at an institution where I studied First M.B. subjects, though this included a large proportion of general science students. Significantly, perhaps, these were composed of the much younger groups. Because such manifestations are the outcome of a psychological immaturity, much might be done by skilful and timely guidance. Young men should be taught to adopt an objective attitude towards social problems, just as they are trained in the impartial handling of professional controversies. If it were possible to reduce the incidence of this revolutionary passion, which I venture to christen the "Emotional Diarrhoea Syndrome of Adolescence," we should almost certainly control a great deal of current and future unrest.—I am, etc.,

London, S.W.10.

J. A. FLETCHER.

SIR,—I am grateful to Dr. G. H. Blair for making his remarks (Dec. 6, p. 931), not because I agree with what he has said, but because it gives me an opportunity of replying and providing certain relevant facts which he either did not possess or overlooked. First, as a result of the B.M.S.A.'s resolution calling for compulsory annual medical examination of clinical students, a meeting was held in Edinburgh on Nov. 26, 1947. Roughly a third (approximately 200) of all clinical students of the University attended, and the following resolution was adopted and carried by a 73% majority of those voting:

"That the clinical students of this University are in favour of yearly compulsory medical examination with provision for genuine objections."

As far as is known no "expert to study and report on student health" has ever been appointed by the medical school, as was suggested by Dr. Blair. I need make no further comment, therefore, about the first part of Dr. Blair's letter.

I should, however, like to explain what the resolution aims at and why it was made. It was felt that in the matter of student health the clinical students should give an active lead to the rest of the student body. The examinations are to be for the benefit of the students themselves and presumably also for the benefit of the public with which clinical students come into intimate contact. It is true to say that almost all students realize the value of thorough medical check-ups, but obviously they are not unanimous about compulsion. The word compulsion has unfortunately acquired a very political significance, and we have attempted in this case to consider it purely on its merits in relation to the problem discussed. In the light of past

experience compulsion seems to be the only possible way in which the majority of students will benefit from the amenities offered to them. This has been adequately illustrated by the provisions made in the University of Aberdeen, where, I understand, medical students are compulsorily examined (no objections have been raised so far), while the students in other faculties have been encouraged to make use of the same facilities voluntarily, the response being about 25%. Recently in a questionnaire to all students at St. Andrews University it was found that a two-thirds majority was in favour of compulsion. In actual fact those who are against the examination itself, not merely against compulsion as such, will still have the chance of objecting in the recognized way, while the compulsion will aim at those who are simply apathetic (still a very large group).

Secondly, I shall deal with the entirely unwarranted attack on the B.M.S.A. This body was formed by, and at the request of, medical students in 1941. It was formed because there are many problems which concern all medical students and also because it was felt that an exchange of views and students between the various schools was highly desirable: this has since been proved to be the case. The headquarters of the B.M.S.A. are in B.M.A. House, London, and all but a few London schools are members. The policy is laid down by the Annual General Meeting and the Association has so far succeeded in concerning itself entirely with matters pertaining to medical students. The work of the Association has now received recognition from most medical students in the country and from very many senior members of the staff, who take part in our many activities. The insinuations of Dr. Blair are without any foundation whatsoever, and before making derogatory remarks of that nature I think one ought at least to be sure of the facts.—I am, etc.,

Edinburgh

S. M. DRANCZ,  
President, B.M.S.A.

SIR,—As one connected with the origins of the B.M.S.A. and as its first president I read with interest Mr. S. M. Drancz's letter on student health (Nov. 22, p. 843) and the reply from Dr. G. H. Blair (Dec. 6, p. 931). The subject of student health has been considered by the B.M.S.A. since its inception, and it would appear to most medical men that there is advantage in a regular routine examination, to include pulmography, for all students at set intervals throughout their career—this not only for their own benefit but to safeguard fellow students against the infectious conditions during the period of university overcrowding. The question of compulsion is debatable but can only be finally settled in practice. I doubt that even a proportion will object, nor can I see a valid objection on the part of the subject provided such examination and medical confidences are not abused.

It was known in 1942, the year the B.M.S.A. was founded, that Edinburgh had an excellent student medical service, as had other schools. This was then thought to be a good reason for spreading the service to include the less fortunate student communities on both sides of the border. This—to me—simple deduction makes Dr. Blair's letter difficult to understand, and the logic of his statement, "An Edinburgh student has no other responsibility than to his own medical school," is not apparent, relevant, or true. I can only be thankful that generations of brilliant Edinburgh students and graduates have not acted on it and have published their advance in system and knowledge to the world at large. I cannot see, nor, I hope, will most people allow, that because an idea comes from outside a particular locality it should be condemned, and I hope that most universities will consider the B.M.S.A. scheme on its merits and not in the limited aspects of Scottish nationalism.

As to the question implied in Dr. Blair's second paragraph, the origins of the B.M.S.A. were never concealed. It began in 1942 as the result of a meeting of London medical schools' representatives who wished, in view of the differences, especially in the clinical years, between medical and other students, to have an organization other than the existing faculty committee of the N.U.S. The B.M.S.A. owed its inception largely to the generous financial and moral support of the B.M.A. and particularly to the encouragement given to its officers by the present secretary, Dr. Charles Hill. I have not had the privilege of reading Sir Ernest Graham-Little's observation on its colour, nor was I aware, either during my presidency or

later, that it had a colour, athletic or political. Looking back on that year my recollection is of a generously multi-hued enthusiasm.—I am, etc.,

London, N.W.6.

IVAN R. CLOUT.

### Sudden Death after Intravenous Injection of Mercurial Diuretic

SIR,—A. G. Oettlé's case of sudden death after intravenous "neptal" (Oct. 4, p. 530) prompts me to a few remarks. Such disasters cannot always be avoided—e.g., if they happen after the first injection to a patient, where there is no reason to expect untoward reactions. Such cases, fortunately, are extremely rare. More often, faulty choice of the case and an overdose are the cause of toxic reactions.

The following rules should help to restrict fatal or toxic reactions. Mercury administration must never be given in excess of the excretory power of the kidneys. Low concentrating power and poor response to a previous injection are warning signals. The minimal injection-free interval should be three days, except in acute emergencies. Digitalis, strophanthin, urea, and ammonium chloride help to make this possible. The dose of ammonium chloride must be adapted to the needs of the case; 15 gr. (1 g.) t.i.d.—the usual dose with many practitioners—is insufficient for most cases. 15 gr. four to six times daily two days before the injection, plus an additional dose of 30 gr. (2 g.) on the day of injection, is needed in most cases. Ambulatory patients should be asked about unpleasant reactions to the previous injection. Warning signals are quite common and most important. Fever is one of them. Patients should rest for half to one hour after the injection before leaving.

Nobody has yet found out why some people tolerate intramuscular mercurials invariably well, while others don't, in spite of local analgesics. Research should be directed towards finding a uniformly well-tolerated mercurial diuretic.—I am, etc.,

Trutnov, Czechoslovakia.

M. WINTERNITZ.

### "Unjustified" Use of d-Tubocurarine Chloride

SIR,—Dr. A. H. Galley's letter (Nov. 22, p. 840) does call for comment, and perhaps the more so because of its title "Unjustified" Use of d-Tubocurarine Chloride." Technical details apart, the account of how even one of the great may be incommoded by the annoyances that beset lesser men is quite gratifying. In most operations the choice and management of the anaesthesia is left entirely to one's anaesthetic colleague: in a caesarean section the technical procedures of the obstetrician have to be closely adapted to the type of anaesthesia being used, and this is my excuse for intruding upon an anaesthetist's argument. Surely Dr. Galley has missed the main point stressed by those who advocate the use of d-tubocurarine chloride for this operation. Its value is that the section can be done with the minimal amount of general anaesthesia and yet with complete control of the patient. If properly administered the patient should regain consciousness as soon as the last stitch is tied. Thereby the special menace of general anaesthesia for this operation is averted. If of course the drug is not used with this object then its use might certainly be termed "unjustified."

The point about the dynamic effects of curare as opposed to thiopentone may be left for further inquiry; myself, I have no doubt in the matter, but Dr. Galley's remarks about relaxation of the abdominal muscles should not go uncontested. To say that anaesthetic muscular relaxation is unnecessary in a caesarean section because the muscles have been well stretched by the pregnancy is surely wrong. Some relaxation must be obtained for a lower-segment operation, and particularly when any general anaesthetic is being given as well; sometimes indeed when the bleeding occurs from torn sinuses on the surface of the lower flap a quiet abdomen becomes an urgent need. The whole discussion certainly is profitable if it serves to emphasize my earlier point, that d-tubocurarine chloride as an adjunct to general anaesthesia in caesarean section can only give its admirable results if both the anaesthetist and the obstetrician know what they want from its use.—I am, etc.,

Liverpool.

PERCY MALPAS.

### Dicoumarol

SIR,—Dr. M. J. Pivawer (Dec. 6, p. 928) complains of anomalous results from prothrombin estimations by Quick's method and states he had to substitute (for prothrombin estimation) clotting time by the method of Lee and White. Prothrombin estimations are the safest guide; and the method of Quick has passed through many hands (and heads) with great benefit. The method we use is only partly modified here, but is very reliable. Important points are (i) use fresh plasma, (ii) conduct the operation at 40° C., (iii) vary the concentration of calcium chloride, (iv) use perfectly fresh viper venom (if possible) guaranteed potency, (v) perform at least six estimations on every sample of plasma, varying the calcium chloride, and report the test giving the shortest time. It may be necessary to do twelve tests on one specimen of plasma, but usually six tests are enough. It is necessary to have a very bright light concentrated on the vessel in which the estimation is being performed, so that the earliest indications of the reaction can be observed. The normal time is 11 to 12 seconds; it is unsafe to allow the time to exceed 30 to 35 seconds.

It is necessary to remember that dicoumarol takes at least 48 hours to act; many failures have been reported because the process of embolism or thrombosis continued unabated after dicoumarol had been given. For immediate effect heparin is unrivalled. Heparin 100 mg. intravenously every four hours for two days is a good introduction for dicoumarol given simultaneously with the first dose. After 36–48 hours the heparin is stopped and the dicoumarol continues the anticoagulant effect. The effect of heparin, though powerful, is transient.—I am, etc.,

Exeter, Exeter.

FRANK MARSH.

### Case of Camphor Poisoning

SIR,—At 1.25 a.m. on a Wednesday in March, 1945, I was called to see a child 2½ years old who was delirious. On crossing the threshold I noticed the whole house smelt of camphor, and the bedroom where slept parents and child smelt strongest.

#### CASE REPORT

The child was sitting up in bed frightened; it obviously saw things which it referred to as "quack-quacks." It was flushed, with a scarlet rash all over the body, limbs, and face, least red on the extremities. The pupils were widely dilated but contracted to the light of a torch. Temperature, 100.2° F. (37.9° C.); pulse and respirations normal; chest clear. Its chest and night clothes were well soaked in camphorated oil. Its bowels had recently opened and it had passed urine.

I was told that the child started with a cold on Saturday evening, and to protect its chest the parents had soaked it in camphorated oil ever since—i.e., for about 80 hours. Diagnosis: Camphor poisoning.

Treatment: There being no better diaphoretic available I ordered hot water with sugar to taste and a very hot bath, which was easily obtainable. While Pater was going to see to this, Mater was to collect the child's night clothes, day clothes, some of its bedclothes, its towel, and everything that smelt of camphor and remove them to the furthest corner of the scullery; open windows and doors, and clear the house of the smell of camphor; then warm up bedroom and provide clean warm bed and night clothes. This treatment was completely successful.

I understand that in 1945 camphorated oil consisted of 1 part camphor and 4 parts arachis oil by weight. Hence 1 oz. (30 g.) of camphorated oil would contain 96 gr. (6.4 g.) of camphor, which, if completely absorbed, would be more than three times the fatal dose for such a child. More than 1 oz. of oil had been used.—I am, etc.,

Lincoln.

G. D. SUMMERS.

### Battle Neurosis Treated with Leucotomy

SIR,—Is reluctance to advocate leucotomy in neurotic conditions really due to "misinformed opinion or theoretical prejudice," as Drs. William Sargant and C. M. Stewart (Nov. 29, p. 866) suggest? In the huge neurosis centres which had been set up in Germany in 1918 when discipline had begun to crack "active treatment" was organized on a large scale with the aim to cure neurotics, if possible, in one session, discharge them home, and employ them in factories serving the war industries.

I worked in one of these centres. On the day of admission patients were given an interview; on the following day under mild ethyl chloride anaesthesia an injection of methylene blue, and, if cured, discharged the day after. 97% of the cases responded to the treatment given. 3% were thought to be incurable. But the study of the psychological make-up of these "incurables" showed that their case was by no means hopeless.

There was a man who had been in bed for over three years suffering from spastic paralysis of both legs, the muscles of which were atrophied to such an extent that it appeared extremely doubtful whether, even after a successful treatment, the patient could possibly stand on them. He had been through all sorts of treatment without any improvement, and the methylene blue had been of no avail either. I decided to give him methylene blue again, but after a different and more thorough psychological preparation. When this man came round from the anaesthetic, and was told to climb down from the table, he did so and walked through the room practically without help. This case became the subject of much controversy; it was argued that the man was a malingerer, as no genuine neurotic with a record of such severity could have been cured by what in the opinion of the critics amounted to a simple appeal to the patient to give up hostility, hate, and distrust and place himself willingly, confidently, and happily into my hands. Of course, the dynamic possibilities of what Freud later described as "positive transference" were not yet understood in those days. The patient was no more a malingerer than the one cured by leucotomy was a compensation neurosis. The methylene-blue treatment was no farce, as was argued, but the bridge of silver over which the patient could walk to health. It legalized, as it were, his surrender before the tribunal of his conscience, or, in psycho-analytical terms, it appeased his superego.

In my experience some sort of magic has always to be employed in cases where a powerful and obstinate superego defeats all ordinary measures of treatment, unless one is prepared to embark on a long course of psycho-analysis. The magic of the methylene blue was not very impressive even in 1918. I could have chosen a better one; and it had failed before. But I wished this case to be a test case for the thesis that our cures were really not due to suggestion, as was generally believed, but to the solving of conflicts. Therefore the suggestion value of the treatment had to be diminished. I could do it because I was dealing with an infantile personality. His superego was open to bribery.

I do not say that leucotomy is no genuine cure for neuroses. I do not know really how it works; so the cure which it brought about may not be due to magic. But I do say that leucotomy to-day is a better magic than methylene blue even was in 1918. It could have been an efficient and suitable appeaser for the patient's more sophisticated superego, though I doubt whether in the later stages of the atom age an enlightened ego would dare to suggest it to his "super" as suitable appeasement. Incidentally, if empirical evidence of *post hoc* cures should be relied upon in preference to theories, it would be more in favour of nasal than of neurosurgery. Therefore practitioners who are called upon to recommend leucotomy against neuroses will have to depend on "theoretical prejudice" after all.—I am, etc.,

London N.W. 11

B. SAALER.

### Tetralogy of Fallot

We are not wishing to underestimate the real value of Mr. J. D. Murray's contribution (Dec. 6, p. 905) to the treatment of Fallot's tetralogy. I feel that there are some points, (a) clinical and (b) historical, which can be challenged. Of the clinical points, I suggest: (1) The "blue malady" is a term which is not necessarily synonymous with the "tetralogy of Fallot"; it refers to any member of the cyanotic group of congenital cardiovascular malformations in which there is persistent cyanosis. (2) Mr. Murray might well have been more correct if he were to have said that, in a patient over the age of, say, 6 years who is suffering from chronic persistent cyanosis as the result of a congenital cardiovascular defect, the "probabilities are about 75% that the diagnosis is the tetralogy of Fallot."

The points of historical interest are largely dealt with by E. Gintrac in a monograph entitled *Observations et Recherches sur la Cyanose ou Maladie Bleue*, published in Paris in 1824. In his book Gintrac mentions some matters of relative interest as follows: (1) His own publication: "Recherches Analytiques sur Diverses Affections dans Lesquelles la Peau Présente une Coloration Bleue, et, en particulier, sur Celles que l'on a Désignées les Noms de Cyanose ou Maladie Bleue" (Collection des Thèses de la Faculté de Paris, 1814, No. 95). (2) The term "morbus cœruleus" which had long been in use by several authors. (3) The term "ictère bleu" as used by many other medical writers was probably a translation of that used by Paracelsus—viz., "icteritia cœlestina seu cyanea"—in his *De Ictericis*, p. 487. Apparently, according to Gintrac, this term, as used by Paracelsus, was not employed with sufficient discrimination to be of any value for "modern diagnosis" purposes. However, there seems to be little doubt that Peacock, whose book *On Malformations of the Human Heart* was first published in 1858, was not the first person to speak of the "blue malady."—I am, etc.,

London, N.4.

I. H. MILNER.

### Penile Carcinoma

SIR.—Dr. D. Preiskel (Dec. 6, p. 928) can hardly expect ritual circumcision to be instituted as a routine measure, in spite of its proven therapeutic value, while prophylaxis against such killing diseases as smallpox and diphtheria is not on a compulsory basis. Surely the "psychological objection to imitating the Jews" is a far-fetched and unwarranted hypothesis. After all, the Christian ritual and religion are of Jewish origin and the insinuation of possible racial prejudice cannot be taken seriously, since we are told—in Luke—that the Founder of Christianity underwent the Abrahamic ritual.—I am, etc.,

Pencoed, Glam.

BEN SAMUEL.

SIR.—The unsupported statement (Nov. 22, p. 841) of even so distinguished a member of the profession as Mr. W. Sampson Handley cannot be taken as proof that the "mixed bacterial flora that flourish beneath the prepuce" can cause or even have caused carcinoma. In the absence of scientific proof to this effect it is, I submit, wholly illogical to attribute a relative immunity to cervical carcinoma possessed by Jewesses to the mutilated condition of their spouses' sexual organs. One might almost as well suggest that the greater Jewish liability to diabetes is to be attributed to ritual circumcision.—I am, etc.,

Launceston, Cornwall.

DONALD M. O'CONNOR.

SIR.—Jewish thought on the relation of man to his Maker dominates the Christian world. In hygienic matters it is equally worthy of attention. The relative freedom of Jewish women from carcinoma of the cervix is almost certainly due to the circumcision of Jewish males. This immunity is not a racial peculiarity, for, as I have shown, it is manifest in the circumcised Fijians, who share Fiji with a separate community of uncircumcised Indians. It is a strange reflection that in this matter the hygienic code of Moses in the dawn of history is still ahead of present standards and that in consequence thousands of women are annually sacrificed to this form of cancer.

Dr. D. Preiskel's letter (Dec. 6, p. 928) suggests that circumcision is an operation of Jewish origin. That is not the case. It is found in independent communities separated by the breadth of the world, but always inhabiting hot climates, where its hygienic advantages became most manifest. It was practised by the Egyptians before the Jews went to Egypt. The oldest known mummy, that of Ra Nefer, destroyed in the bombing of the Royal College of Surgeons in 1940, had been subjected to the operation. It was practised in Arabia, and Abraham learnt its advantages from his Arabian wife Zipporah, who circumcised their son. His broad-minded adoption of the operation for himself and his descendants is an example of freedom from racial prejudice worthy of imitation.

But except for the phimotic with a long prepuce it can be replaced either by meticulous cleanliness, or more certainly by

preputiotomy. Dr. Preiskel's criticisms of this latter simple operation appear to show that he has never performed it. The clumsy lateral flaps of prepuce left by it so atrophy and retract that in a few years the result is practically indistinguishable from a circumcision, though no tissue has been removed.—I am, etc.,

London, W.1.

W. SAMPSON HANDLEY.

### Foreign Body in the Vagina

SIR.—The unusual nature of the following case makes it worthy of publication.

The patient was a widow aged 60 years who wore a 2½-in. (6.3-cm.) watch-spring pessary for prolapse. The ring had not been changed for a year, and she complained of an unpleasant vaginal discharge and slight discomfort in the left iliac fossa—this latter being present for two weeks. On questioning her with regard to douching I elicited the fact that she had been in the habit of douching with a weak solution of "lysol," using a bone-nozzle enema syringe. She had last done this three months ago.

I removed the ring with some difficulty with the patient lying on her right side and with her knees drawn well up (I am left-handed), and thought at the time that there was something peculiar about the ring—namely, that it appeared to have an irregular bar fixed across its centre. When it was removed I found the "bar" to be the bone nozzle of an enema, which had become firmly jammed across the inner diameter of the pessary. On questioning her as to whether she had ever mislaid the nozzle of the enema she said that she had—*nine months ago*. She added that the reason she did not suspect the whereabouts of the nozzle was that she thought she had seen the cat playing with it at about the time that it was lost.

My reason for writing the above note is to show how long a foreign body of moderate size may be retained in the vagina without producing symptoms of any severity.—I am, etc.,

London, S.W.4.

G. J. GRAINGER.

### Asthma and the Inhaler

SIR.—It is agreed that the treatment of patients suffering from bronchial asthma is a real problem, especially during the winter months. The inculcation of a careful regime and breathing exercises rarely, if ever, succeeds in warding off attacks, and patients have to resort to antispasmodics. Apart from some expensive proprietary preparations most antispasmodics are associated with troublesome side-effects in a large number of asthmatics, and these unfortunates dread the treatment as much as their affliction.

The modern inhaler with inhalant proves a godsend to these patients, and the results from the doctor's point of view are most gratifying. The important point is that the doctor must teach the patient how to use and maintain the inhaler, and apart from treating the attack I advise the use of the inhaler three times daily during a flare-up of acute bronchitis. Simply to prescribe the inhaler is an utter waste of time, and there must be many of them locked away in cupboards and regarded as useless because the patients have not been taught their correct use. Personally I keep one in the surgery for demonstration purposes, and the few minutes thus expended pay dividends not only in the gratitude of the sufferer but also in reducing emergency calls. A small proportion of patients cannot be taught to use the inhaler.

Doubtless there are cases of severe asthma requiring injection of antispasmodics, but I think that the doctor will find that most of his emergency calls will respond to the inhaler if he cares to carry it in his bag.—I am, etc.,

St. Helens, Lancs.

JAMES KAY.

### Food Cuts and Calories

SIR.—It is indeed timely that such figures as those of Dr. G. T. Mills (Dec. 6, p. 926) should be published. For too long now has this country been stuffed up with the half-truths and misrepresentations of the Ministry of Food. By using "calories" as a basis of nourishment the M.O.F. gives an entirely false picture—a bottle of whisky a day will supply all the required calories. As is pointed out, the actual calories obtained from our diet are nothing like those promised and even less like those needed. Perhaps this accounts for the poor resistance of the population to minor infections and their lack of physical stamina.—I am, etc.,

Coventry.

JOHN HALE POWER.

### Foetal Cries

SIR.—I was interested in the cases of vagitus uterinus which have recently been described in your correspondence columns, particularly with Dr. Jean Burton-Brown's letter (Oct. 25, p. 672), in which she mentions 123 cases occurring between 1800 and 1941. The phenomenon, however, has been known for well over 2,000 years. In book xxiv of Livy's *History of Rome* he records a case which occurred in Italy during the critical days of the second Punic war in 214 B.C. On this occasion the Romans were encouraged by a foetal cry of "Io triumphe" to persevere and ultimately overcome the fears and trials of their time. It is to be regretted that foetal cries of to-day, interesting though they may be, contain no encouragement for us to endure our present hardships.—I am, etc.,

Isleworth, Middlesex

C. W. F. BURNETT.

### Future of Almoners

SIR.—As practising hospital almoners we should like to comment on Dr. Trevor H. Howell's letter (Nov. 22, p. 843) on the care of the "chronic sick" by almoners when the new National Health scheme comes into force. May we first correct the implication that almoners cherish "their money bags" and regard assessment or collection as their main function? In hospitals where almoners have not yet been able to shake off this millstone they anticipate the new scheme with joy because it will leave them free to carry out the job for which they have undergone an intensive training—i.e. to do social work in co-operation with the medical staff to facilitate the patient's recovery.

It is true that we may be free to do more for the "chronic sick," but in many hospitals a great deal is already done. The main difficulty is that our scope is severely limited by the lack of suitable old people's homes or domiciliary nursing services. While we are willing and anxious to do all we can to relieve the often unpleasant and pathetic lot of the aged sick folk, the magnitude of the problem far exceeds the resources at our disposal. The difficulty lies not so much in almoners' being so busy with money bags that they have no time for caring for the chronic sick, as that there are inadequate voluntary or statutory provisions for their care.—We are, etc.,

M. CHAVE JONES.

M. EPPS.

Wallington, Surrey

### Pulmonary Tuberculosis in Austria

SIR.—Only recently I happened to see Dr. A. Macfarlane's letter (Aug. 30, p. 348) containing rather far-reaching conclusions regarding the effect of undernourishment on tuberculosis. Unfortunately the figure given for 1945 is not correct. In 1945 there were 7,269 deaths from pulmonary tuberculosis in Austria and not 5,043. The corresponding figures for Vienna are as follows:

Year	Deaths from Pulmonary Tb
1940	2,146
1941	1,957
1942	2,337
1943	2,230
1944	2,393
1945	3,734
1946	2,379

The drop in 1946 can only be explained in one way. In 1945 under the stress of hunger, overcrowding, lack of hospital accommodation and medical attention a great number of cases have died who under normal conditions should have lived some more years. In my opinion this will be felt in 1947 and probably in 1948. The number of newly discovered cases of pulmonary tuberculosis has been increasing steadily since January, 1946. Clinical experience indicates a close connexion between undernourishment and the incidence of primary tuberculosis in young people and the flare-up of inactive disease in older persons. I do not think that the death rate and the morbidity in Vienna allow to abandon proved views and to build up a new theory on the effect of undernourishment on tuberculosis.—I am etc.,

Public Health Department, Vienna.

A. FISCHER,  
Chief Tuberculosis Officer.

**Alleviation of Prickly Heat**

SIR.—I have read your annotation on prickly heat (Nov. 15, p. 779) and should like to mention a method of alleviation of this annoying complaint which is very effective and dramatic in its action, although it is not a cure, nor does it supersede any methods which are known to be effective in its prophylaxis or cure. I am referring to the beneficial effect of "benadryl." Within the space of several hours of taking 100 mg. of benadryl there is a blanching of the affected area and a concomitant relief from the intense itching. A short course of benadryl lasting 1-2 days is able to cause a complete remission of symptoms, but naturally in an adverse climate there will be a recurrence. I presume that other antihistamine drugs will act similarly. I should be very grateful to hear of anyone's experience of this method.—I am, etc.,

Nedley, Hants.

LEON RADCLIFFE.

**Diet and the Nation's Health**

SIR.—In the debate of the Hunterian Society on Nov. 17 (*Journal*, Nov. 29, p. 882) the dietitians fought a losing battle on the issue "That our present diet is undermining the health of the nation." Mr. Dickson Wright stated that the assembly looked a well-fed one—not a very scientific remark, as his audience were in a favoured position to keep so, and I doubt very much whether he himself was living on the calorie level he suggested as adequate for others.

Sir Jack Drummond gave an account of the robust health of our present-day children. He never mentioned their mothers who nowadays are unable to suckle their own progeny for more than a week or two and then have to turn to dried milk, orange juice, and cod-liver oil or substitutes. I suppose these substitutes are better than the real article and will build better Britons than their grandparents. In addition these self-sacrificing mothers who give up their meagre rations to keep their children healthy are now called upon to do extra factory work. The dietitians are trying to flog a dying horse, dying of malnutrition without hope or energy.—I am, etc.,

Woodley, Cheshire.

J. G. BENNETT.

**POINTS FROM LETTERS****What is a Psychiatrist?**

D. J. B. GURNEY SMITH (Epsom, Surrey) writes: Having reference to the recent correspondence on the M.R.C.P. and specialists and the D.P.M., I should be very glad to know what is a psychiatrist.

It would seem that there are many medical men definitely engaged in psychiatric work calling themselves psychiatrists who have no real right so to style themselves. A surgeon is usually the possessor of the F.R.C.S. or M.S. and a physician the M.D. or M.R.C.P. Surely all psychiatrists should be diplomats in their particular subject? I shall be glad of any official and informative views on this subject.

**Hospital Treatment of School-children in Shropshire**

Dr. CLAUDE E. TANGYB (Truro, Cornwall) writes: This correspondence must have roused great regret. With the advent of the National Health Service it is more than ever vital that there should be complete accord between the general body of practitioners and the medical officer of the authority. . . . I would like to suggest that such difficulties can be avoided by the appointment of a medical advisory committee. Over more than a quarter of a century in Wiltshire such a committee, appointed by the County Branch, was of the utmost value to the profession and myself. It ensured that in presenting any proposal to the authority affecting practitioners I could rely on the support of the profession, since a free and informal discussion had already taken place at the medical committee and agreement been reached. I take this opportunity of putting on record my gratitude to those who came so regularly and so cheerfully from all parts of the county to collaborate with me. . . .

**Companions of St. Luke**

Dr. ISABEL PULTENEY (2, Bryanston Place, London, W.1) writes: Some of the readers of the *Journal* may be interested to know of the existence of the Companions of St. Luke. This is a society of women doctors and medical students, communicant members of the Church of England, which has as its aim the mutual support of the members in leading a Christian life and the spread of the Catholic faith. The numbers are at present small and inquiries are welcomed from any who feel themselves to be in sympathy and would like further information. The Constitution allows of the admission of men students and doctors, either as a separate ward or as a mixed body; we shall be glad of suggestions on this point.

**Obituary**

CHARLES BOLTON, C.B.E., M.D., D.Sc., F.R.S. F.R.C.P.

With the death of Charles Bolton on Dec. 6, at the age of 77, the profession loses one of its remaining links with that vigorous Edwardian period when general consulting practice and fundamental laboratory research did not appear incompatible. The start had not been easy for him. A Yorkshire lad from Whitby, he was apprenticed there at 16 to a local doctor for three years, and then to a Manchester practitioner for a further two years. Guided perhaps by the success of his elder brother, he used his time as an apprentice so well that at the age of 21 he was able to enter for the medical course at University College, London, with an exhibition of £100 a year. The scientific atmosphere he met there was at first an astonishment and soon a life-long inspiration to him.

He took the London B.Sc. in 1894 and graduated M.B., B.S. two years later. After holding resident appointments at his own hospital under Sir Rickman Godlee and Dr. Frederick Roberts, he became resident medical officer to the Evelina Hospital for Children and, thereafter, assistant medical officer at the Eastern Fever Hospital during the distinguished superintendence of Dr. E. W. Goodall. He then returned to University College Hospital, where for three years he was resident medical officer. Two years later he was appointed to its staff as assistant physician, became physician in 1912, and consulting physician in 1935. In 1908 he gained the D.Sc. degree; he was elected F.R.C.P. in 1909, F.R.S. in 1918, and he was awarded the C.B.E. in 1920. In 1911 he married Ethel, daughter of the late Henry George, and, although he had no children, the family medical tradition begun by him and his brother, the late Joseph Shaw Bolton, professor of mental diseases in the University of Leeds, is carried on by his nephew and niece.

Bolton was peculiarly fortunate in the period of his training, for he came to University College when it housed a galaxy of talent in its medical faculty. The medical school had not then been separated from its parent body and the faculty at University College combined both clinical and preclinical subjects and housed all the laboratories. Thane and Schafer were at the height of their powers. On the clinical side were Ringer, Barlow, Rose Bradford, Victor Horsley, and Sidney Martin, and at that time Horsley and Bradford were in the full flood of active research. A little later Bayliss and Starling joined the staff. It is not surprising that in this atmosphere Bolton should have had his scientific enthusiasm aroused and should have acquired that habit of mind which he retained through his whole life—the habit of research into the mechanism of phenomena. But he did not diverge into physiology. Perhaps his early apprenticeship in general practice determined his road, for it was to pathology he turned, and in this he was largely influenced by the writings of Cohnheim. His first researches were undertaken while he was at the Eastern Fever Hospital, where he demonstrated that in typhoid fever the infecting organism could pass the placenta and infect the foetus, and that in fatal diphtheria chromatolysis occurred in the medullary nuclei.

In 1903 he was awarded a Grocers' Company research studentship for six years, and thus obtained the desired freedom for laboratory work. His earlier interest in the mechanism of bodily function now reasserted itself, and, stimulated by clinical observations on a case of constrictive pericarditis, he began a long series of investigations into the nature of dropsy. In these he was far ahead of his time, in

fact only now is the essential correctness of his views beginning to be appreciated. Two examples will suffice to show this. Over thirty years ago Bolton clearly stated that the oedema of cardiac failure could not be accounted for by increased venous pressure but that the prime factor in this condition was a change in the permeability of the capillary wall. It is only recently that the work of Landis on the effects of stagnant anoxia on capillary permeability has vindicated Bolton's views. Again, Bolton showed that the centrilobular damage in the nutmeg liver of cardiac failure was not due to back pressure but was the result of an active necrosis in the parenchymal cells. Large as this subject was, it was not his only research interest. In 1904 he published the first of his important papers on gastric ulcer; he used specific gastrotoxins in order to produce a localized ulcer in animals. This led him to the proof that gastrotaxins produced no visible damage in the stomach's cells unless they were exposed to acid gastric juices. Neutralize the acidity and no ulcer results; augment it and the lesion extends, though it never becomes a chronic ulcer like that seen in man. It was on the basis of these observations that he shaped his therapy of peptic ulcer and substantiated it by a monumental research on the clinical aspects of this condition.

By the middle of the first decade of this century Bolton's reputation as an investigator was established, and in 1907 an event occurred which gave him the opportunity he deserved. University College Hospital Medical School separated from its parent body, University College. The new school had acquired its own research facilities and a director was needed. In 1908 Bolton was appointed, on a part-time basis, as the first director of the Graham Research Laboratories. Two years later he was appointed to the lectureship in pathology, which made him responsible for all pathological teaching and work in the school. These posts he continued to hold until 1914, when, their duties having grown greatly, they were merged in a single whole-time post to which the late Prof. A. E. Boycott was appointed. Then came the first world war. Bolton took charge of the military wing at University College Hospital and became fully immersed in clinical practice.

With the close of the war the second period of Bolton's life began. His reputation as a clinician had advanced to equal his reputation as an investigator. He now reaped the rewards—or penalties—of distinction: he was in demand. His practice grew widely, not only in regard to his particular interest in peptic ulceration, but in general medicine. Yet it was characteristic of the man and his generation that, although accepting the rewards of his reputation, throughout the whole of this busy period, and until his retirement, he reserved one afternoon a week for research. Then he would be found in his laboratory with old John Vandome in faithful attendance. Cigarette in the corner of his mouth, smoke curling into his eyes, he operated on his animals with a casual deftness that was in surprising contrast to his large frame and deceptively slow manner.

Behind this record of solid achievement as a practising physician, as an investigator, and as a teacher lay a massive personality. Bolton was a man of singular concentration. Embarked on a line of thought, he pursued it with an undeviating momentum which rendered him cheerfully impervious to all distractions. But once his attention was captured the questioner received a scrutiny as intense as the preceding abstraction and found himself cross-examined with a relentless precision that soon got to the root of the matter. Yet there was nothing of the unapproachable about Bolton. He was the most friendly and cheerful of souls. Add to this a dry humour, as native to Yorkshire as his accent, and the secret of his personal popularity is not far to seek.

#### ROBERT A. FLEMING, LL.D., M.D., F.R.C.P.Ed.

Dr. Robert Alexander Fleming died at Innerhadden, Kinloch-rannoch, on Dec. 5, at the age of 85. A native of Dundee, he graduated M.A. at Edinburgh University in 1884, and M.B., C.M. with first-class honours in 1888. He also studied at Vienna and Berlin, became a Fellow of the Royal College of Physicians of Edinburgh in 1892, and took his M.D., with a gold medal, in 1896.

A long connexion with the Edinburgh Royal Infirmary began in 1897 when he was appointed pathologist, and in 1900 he became an assistant physician. He was made a junior physician in 1913 and senior physician in 1919, with charge of wards. He was also senior lecturer in clinical medicine at the University. When he retired from the Royal Infirmary in 1927 under the age limit he was appointed consulting physician, and thus maintained his link with the hospital for a further twenty years. As a Territorial officer he saw active service with the Salonika Expeditionary Force when over the age of 50 as a major in charge of the medical division of the 2nd Scottish General Hospital, and also with the 42nd General Hospital. He was later surgeon to the King's Bodyguard in Scotland, Royal Company of Archers.

During the course of a long medical career he held many appointments, including that of physician to the Royal Edinburgh Hospital for Incurables, examiner in medicine for the Royal College of Physicians of Edinburgh, and medical adviser to the Prison Commissioners for Scotland, in which capacity he interested himself particularly in Borstal and other reform institutions. In 1927-9 he was president of the Royal College of Physicians of Edinburgh, and was honoured by the University of Edinburgh in 1928 with the degree of LL.D. His publications included a *Short Practice of Medicine* in 1919, and he wrote a number of articles on diseases of nervous and respiratory systems. A member of the British Medical Association since 1889, he was secretary of the Section of Neurology in 1898, and vice-president of the Section of Medicine at the annual meeting in Edinburgh in 1927. He was a Fellow of the Royal Society of Medicine, and a Fellow of the Edinburgh Royal Society. As a clinician and teacher he will be remembered by his colleagues and former students for his quiet and kindly personality, and for his ready sympathy. With a wide circle of friends, and a keenness for archery, shooting, and fishing as recreations, he remained in active professional work until a few months before his final illness. He is survived by Mrs. Fleming, three sons, and a daughter.

#### JULIAN AUGUSTUS ROMAINE SMITH, M.D.

We record with regret the death of Julian Augustus Romaine Smith on Nov. 13 at Melbourne. He was one of the most versatile men who have practised medicine in that city. Born in Surrey in 1873, he went early in life with his parents to South Australia. He was educated at Prince Alfred College, Adelaide, obtained the B.Sc. degree at Adelaide University at the age of 19, and returned to Prince Alfred College as mathematical and science master. Medicine attracted him, however, and he began studying it at the University of Adelaide. At this time, as the result of a dispute with the Government of the day, the teaching staff of the Adelaide Hospital resigned in a body. In order to complete the course some of the senior students went to Sydney; others, including Julian Smith, to Melbourne. He qualified in 1898 after gaining first place in every examination for which he sat. He rowed twice for Adelaide University in the inter-university boat races and later coached the Ormond College (Melbourne University) crew. His language as a coach has become a legend, and his dark piercing eyes seemed to bore through oarsman or student who failed to reach the quite attainable standards expected of him; but the dawning smile which ultimately irradiated his face held his victim's affection.

As appointments to the resident staff of the Melbourne Hospital are made according to the position of the graduates in the final honours list, he became senior resident officer. Not only was he a most original teacher but he had the skill to read blue-prints and the manual dexterity to construct complicated technical apparatus. For example, soon after x rays were discovered and drawings of machines were available, Julian Smith—having undertaken for a few years a practice in a country town where there was no electric current available—made a Wimshurst generating machine and produced excellent x-ray negatives with it. Being invited to join the staff of St. Vincent's Hospital he returned to Melbourne, and here his great ability found full scope. He studied biochemistry as it evolved and made use of it in his practice. He learnt the technique of cystoscopy in its earliest days and played his part

in raising the efficiency of diagnosis and the standard of urological surgery. When Almoth Wright published his first work on the opsonic index Smith came to England to determine its value at first hand. As elsewhere in the world at that time hygienic measures had scarcely begun to lower the incidence of surgical tuberculosis, and many patients were sent to Australia because of its excellent climate. Smith, although an accomplished surgeon, was never content to accept a traditional operation as the final word and ever hopeful of finding a cure by means more rational than surgery. Later, when Ronald Canti made his first film of tissue culture, Smith visited England again to see this and to learn what progress was being made in cancer research. Meanwhile he carried on a large surgical practice with a fine clinical mind, balanced judgment, and technical skill. He exacted from his students what he practised as a habit in his own work—careful clinical examination controlled by relevant laboratory methods.

During his long experience of peptic ulceration, which began with the dawn of gastric surgery in Australia, he became convinced that blood transferred direct from a donor was more effective than citrated blood in controlling haemorrhage. With his skill in making or adapting apparatus he modified the "Frankfurt" rotary pump, had his own connexions and needles made, kept the latter flawlessly sharp, and collected and grouped donors. At first he employed this method for his own patients and those colleagues who desired it at his own hospital. As with increasing years he gradually relinquished general surgical work he applied himself with missionary zeal to transfusion. He gave his time and strength to organizing the method of direct transfusion for the teaching and the military hospitals in and around Melbourne. With battle casualties returning, as well as the demands of civilian practice, many physicians and surgeons gladly availed themselves of his services. He continued this work for several years after his 70th birthday. He was also elected an honorary Fellow of the Royal Photographic Society; he exhibited regularly at the exhibitions of that society, at the London Salon of Photography, and in America.

Julian Smith was singularly free from personal ambition—certainly of its more vulgar manifestations. His investigations of other methods of treatment never turned him from the teaching and practice of sound surgery. They were evidence of his restlessly inquiring mind, satisfied with nothing that seemed to him capable of improvement. He was a very lovable man. He is survived by his wife, three sons, a daughter, and the affection of the whole profession and inhabitants of Melbourne and Victoria.

Dr. CECIL BERESFORD HOGG, medical officer of health of Kettering, died in the Middlesex Hospital on Nov. 26 at the age of 57. He graduated M.B., Ch.B. at Aberdeen University in 1914, and proceeded M.D. in 1925, obtaining his D.P.H. in 1922. After serving with the R.A.M.C. during the 1914 war, he was appointed senior assistant medical officer at the Monsall Fever Hospital, and later held a similar appointment at the Royal Hospital for Consumption, Ventnor. He then became senior assistant medical officer of health and assistant school medical officer for Blackburn. In 1930 he was appointed the first whole-time medical officer of health and school medical officer for Kettering. In addition he was medical superintendent of the Kettering Joint Board Infectious Diseases Hospital and medical referee to the Kettering crematorium. Dr. Hogg published a number of papers on such subjects as artificial pneumothorax, paratyphoid, and Sonne dysentery. He was a fellow of the Society of Medical Officers of Health, and will long be remembered by his colleagues, with whom he was working until six weeks before his death. He is survived by his widow and one daughter.

A. T. J. writes: I should like to pay a tribute to the memory of the late Sir John Fraser. We cannot realize that he has gone from us, as he appeared to have a strong physique and vigour and seemed to be a real picture of health and strength. I may say that he was the most charming man I ever met, so genial, kind, and sympathetic. He had the well-being of everyone who contacted him at heart, and I know he always wanted to give every assistance to all who appeared before him. His death will be a loss to Edinburgh and especially to the University, in which he held the honourable position of principal. He has well deserved the honours bestowed upon him by His Majesty the King, in which honours all his friends

and acquaintances rejoiced. We revere his memory and realize the great loss which the community and especially his family have sustained. He has gone from his labour to his reward, and I personally mourn with all who knew him.

## Medical Notes in Parliament

### Medical Practitioners and Pharmacists Bill

The Medical Practitioners and Pharmacists Bill, which had already passed the House of Lords, where its provisions for admitting foreign practitioners to the United Kingdom Register had been fully expounded, came up for second reading in the House of Commons on Dec. 5.

Mr. ANEURIN BEVAN recalled that before and during the war a number of doctors from abroad came to this country but had been unable to practise until special arrangements were made under Defence Regulation 32B of July, 1940. That temporary register had been closed in February, 1946, but doctors on that register continued to be registered till Dec. 31, 1947. After that they would be unable to practise unless the position was regularized. At the same date Polish doctors temporarily registered under the Polish Resettlement Act would cease to be registered. Some of these, however, might not be in Britain at the end of the year. He estimated that about 1,500 to 2,000 doctors would want to avail themselves of the facilities under the Bill. About 200 Polish doctors brought here under the Polish Resettlement Scheme had registered, and this figure would have increased by the end of the year. The Bill would also cover graduates of the Polish School of Medicine, Edinburgh, and other doctors who arrived here owing to war circumstances before Aug. 4. Aug. 4 was the date on which the intentions of the Government had been made known.

Mr. WALTER ELLIOT said that the Conservative Opposition proposed to afford every facility for the passage of the Bill. He trusted it would be possible to go a little further and to extend the arrangements for reciprocity. Relaxation of our stringent conditions, even as regards distinguished physicians from the New World, would be of great advantage.

Mr. SOMERVILLE HASTINGS said the Bill arose at the suggestion of the British doctors themselves, who were willing to give up exclusive possession of facilities to practise obtained by six years of hard study, to reward doctors from abroad who had served the country well during the war. He was grateful to the Minister for agreeing with the medical profession and he hoped the profession would reciprocate by agreeing with the Minister in the negotiations now proceeding. He felt some doubt about Clause 81, which conferred a temporary right to practise on persons from abroad who satisfied the General Medical Council that they intended to be in the United Kingdom temporarily for employment in a medical capacity in a hospital or other institution approved by the Council. The Clause would allow doctors from abroad who came here for postgraduate instruction at the hospitals and medical schools to take jobs as house-surgeons. Some doctors who came to this country did not reach the standard of men and women qualified here. Patients in the ward of a hospital would be placed in the charge of one of these doctors and would have no choice in the matter. The Clause should be recast to say "demonstration and instruction" instead of "employment," and "a teaching hospital" instead of "a hospital." He thought Parliament was giving the General Medical Council too much power in this Bill.

Sir HENRY MORRIS JONES did not agree that the generosity of British doctors to foreign doctors justified an appeal to the former to show equal generosity in accepting the provisions of another Act to which many of them objected. He drew attention to Clause 4 under which many would come in whose capacity for general practice was little known. He suggested they should undergo an *ad hoc* examination to protect the public.

Mr. BEVAN, replying to the debate, said he was pleased with the reception given to the measure. He was grieved, however, at Mr. Somerville Hastings's remarks on postgraduate medical education. They had not enough postgraduate facilities now, but could make London, Edinburgh, and Great Britain generally the medical Mecca of the world. There would be provisional registration of doctors not on the temporary register so that their experience and knowledge could be tested before they were permanently registered.

The Bill was read a second time.

### Professional Freedom

Mr. House asked on Dec. 4 whether the attention of the Minister of Health had been directed to evidence recently given

at an inquest at St. Pancras that Henry William Maryon died within three minutes of being given an injection of congo-red dye by a medical practitioner; and would he take steps to stop this practice of injecting drugs.

Mr. BEVAN said he had heard of this unhappy case. Accidents due to this cause were extremely rare. The injection of drugs had for years been an essential part of modern therapy, and there was no reason to think that its discontinuance would be anything but a disadvantage in the public interest. Nor was it his proper province to prevent doctors from using their free clinical judgment to the best of their professional ability.

*Industrial Health Research.*—Mr. HERBERT MORRISON said on Dec. 8 that the expenditure of the Medical Research Council on that part of the programme in which it was advised by the Industrial Health Research Board amounted to £161,520 over the last four financial years. During the same period twelve reports on this work had been published officially and forty-six other reports as contributions to scientific journals. The policy was to continue the expansion which had already taken place on a considerable scale since the war.

## EPIDEMIOLOGICAL NOTES

### Poliomyelitis

In the week ended Dec. 6, for the first time since the week ended July 5, notifications of poliomyelitis, 70 (103), were below the peak figure for 1938 of 85 notifications in the week ended Oct. 22, 1938. The fall from 103 to 70 maintained a more rapid rate of decline which has been noticeable since the week ended Nov. 15, and if this rate continues notifications should be reaching the usual winter level of 4 to 5 cases a week by the middle or end of January.

### Discussion of Table

In *England and Wales* an increased incidence was recorded for cases of measles 539, whooping-cough 330, acute pneumonia 64, cerebrospinal fever 14, paratyphoid fever 14; the only decreases were dysentery 64 and scarlet fever 47.

An increase in the notifications of measles was recorded in most areas, the rise in the North being greater than in the South; the largest increase during the week was Glamorgan-shire 64. Cases of whooping-cough were more numerous throughout the country; the largest increase in notifications was Yorkshire West Riding 68; the only exception of any size to the general increasing trend was a fall in Lancashire 59.

The 44 cases of cerebrospinal fever were notified from 17 counties, the largest local returns being Birmingham C.B. 4 and Liverpool C.B. 5. Seven of the total of 18 cases of paratyphoid were notified in Yorkshire West Riding, Kirkburton U.D. Only small variations occurred in the returns of scarlet fever. The largest fluctuation in the notifications of diphtheria was an increase of 10 in Durham. Only 3 further cases of dysentery were notified from the outbreak in Berkshire, Wallingford R.D., and no further case from the outbreak in Staffordshire, Willenhall R.D. The largest returns of dysentery were Lancashire 24 (Liverpool C.B. 14) and London 14.

The cases of poliomyelitis were widely dispersed throughout the country, the highest totals of notifications being Lancashire 12 and Surrey 11. The largest number of notifications in an administrative area was 9 in Surrey, Hambledon R.D.; the other seven administrative areas with more than 1 case notified had only 2 or 3 cases.

In *Scotland* increases were recorded in the notifications of measles 159, dysentery 25, scarlet fever 23, and acute primary pneumonia 17. No large increases occurred. Notifications of measles in Glasgow were 303, compared with 155 in the preceding week, and an increase of 20 was reported in the notifications of dysentery.

In *Eire* only 190 cases of measles were notified, 68 fewer than in the preceding week. In Dublin the number of notifications fell by 30, and no further cases were reported from Waterford, Dungarvan U.D., where 43 cases were notified in the preceding week.

In *Northern Ireland* the notifications of measles increased by 18.

### Week Ending December 6

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 2,027, whooping-cough 1,488, diphtheria 205, measles 2,799, acute pneumonia 530, cerebrospinal fever 46, acute poliomyelitis 70, dysentery 93, and paratyphoid 8.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov. 29.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## Canadian Red Cross Memorial Hospital

At an "At Home" for local medical practitioners held at the hospital on Dec. 6, presided over by Mr. Ralph Marnham, Director of the Department of Surgery, Sir Francis Fraser spoke on "Post-graduate Medical Education at a Hospital Centre." Sir Francis referred to the association of the hospital with a university centre and of the various forms of postgraduate education which might be developed under the new Service. Dr. E. G. L. Bywaters, Director of the Special Unit for Juvenile Rheumatism, Dr. G. D. Hadley, Director of the Department of Medicine, Dr. L. E. Glynn, Director of the Department of Pathology, and other members of the medical and surgical staff of the hospital were present, and the wards and departments of the hospital were open to visitors.

## New President for Tuberculosis Association

Dr. F. R. G. Heaf has been elected President of the Tuberculosis Association. He is Honorary Consulting Medical Director of the British Legion Village at Preston Hall, near Maidstone, and Nayland Sanatorium, near Colchester, where ex-Service men and women suffering from pulmonary tuberculosis are treated.

## Leprosy Research

Prof. John Lowe, of Calcutta University, has gone to Nigeria to institute research into the treatment of leprosy by sulphones.

## COMING EVENTS

### Conference on Remedial Gymnastics

The Ling Physical Education Association (Hamilton House, Bidborough Street, London, W.C.) has arranged a conference on remedial gymnastics at Sloane School, Hortensia Road, Chelsea, London, S.W., on Monday, Tuesday, Wednesday, Thursday and Friday, Dec. 29, 30, and 31, 1947, and Jan. 1 and 2, 1948. The programme opens at 9.30 a.m. on Dec. 29 with a lecture by Dr. Harold Balme on "The Place of the Remedial Gymnast in the National Health Scheme." Contributions by other members of the medical profession are as follows: Dec. 29, 1.45 p.m., Dr. Doris M. Baker, lecture-demonstration on "Remedial Treatment in School of Children with Postural Foot Defects." Dec. 30, 1.45 p.m., lecture by Prof. A. B. Appleton, "Feet and Posture"; 2.50 p.m., Dr. Doris M. Baker, lecture-demonstration on "The Medical Significance of Postural Valgus Deformity of the Foot." Dec. 31, 9.30 a.m., lecture-demonstration by Dr. F. S. Cooksey, "Postural Defects of the Spine in Childhood and Adolescence"; 11.20 a.m., lecture by Dr. Maud F. Forrester-Brown, "Team Work in the Prevention and Cure of Postural Defects." Jan. 1, 4.35 p.m., Dr. J. L. Dunlop, "The Place of the Educational Gymnast in a School Health Service." The fees are: whole conference (including travelling expenses to various institutions), £2 2s. (if paid in advance) or £2 5s. (if paid at conference); per day, 14s. or 15s.; single session, 3s.

## APPOINTMENTS

The Minister of Health has made the following appointments to Regional Hospital Boards:

**Oxford.**—Mr. H. A. Goddard, Welfare Officer of Morris Motors Ltd., member of the Committee of the Radcliffe Infirmary and vice-chairman of the local hospitals contributory scheme, to fill the vacancy caused by the resignation of Prof. Seddon owing to pressure of other work.

**South-western.**—Mr. W. J. Carter, chemist at the Imperial Smelting Corporation and one of the workers' representatives on the board of the Bristol Royal Infirmary, to fill the vacancy caused by the resignation of Major Egbert Cadbury owing to pressure of other work.

**Sheffield.**—Dr. J. G. McCrie, Dean of the Faculty of Medicine of the University of Sheffield, to fill the vacancy caused by the resignation of Prof. E. J. Wayne.

## BIRTHS, MARRIAGES, AND DEATHS

### BIRTH

**Stanbridge.**—On Dec. 2, 1947, at No. 8 R.A.F. Hospital, Germany, to Inez Holland, wife of Group Captain R. H. Stanbridge, O.B.E., a son.

### DEATHS

**Larson.**—On Nov. 30, 1947, at 621, Loughborough Road, Birstall, Leicester, John Richard Larson, M.B., Ch.B., aged 54.

**Mamlock.**—On Dec. 6, 1947, at Musgrove Park Hospital, Taunton, Somerset, Harold Charles Mamlock, M.D.

**Stone.**—On Dec. 9, 1947, at The Stone House, Rose Hill, Dorking, Surrey, William Gream Stone, M.D., F.R.C.S., aged 81.

## Syphilis in a Nursing Mother

**Q.**—When an apparently healthy full-term baby is born of a mother who in the second month of pregnancy had a positive blood Wassermann reaction, for which she received the usual antisyphilitic treatment during the remainder of her pregnancy, is it advisable to administer antisyphilitic treatment to the baby, despite a negative serological test for syphilis, or is one justified in waiting until tests become positive or the baby develops clinical evidence of the disease? Can the breast milk of a clinically healthy woman with a positive serological test be fed with impunity (a) to her own baby who is clinically healthy and sero-negative, and (b) to someone else's baby who is apparently healthy and in whom there is no reason to suspect syphilis? Is it likely to make any difference whether the woman has or has not had antisyphilitic treatment?

**A.**—The sero-negative baby of a sero-positive mother should not receive antisyphilitic treatment merely because the mother's Wassermann reaction was positive. The baby should be kept under careful observation and its blood should be tested once a month for six months. If at the end of this time the baby shows no clinical or serological signs of syphilis it can be considered free from infection. The treatment given to the mother may well have been sufficient to protect the child but not to reverse the Wassermann reaction of the mother. A syphilitic woman may suckle her own baby even though it appears free from syphilis, but she should not suckle someone else's healthy baby. Apart from the possible presence of spirochaetes in the breast milk, the organisms might be conveyed through a cracked nipple. Previous treatment, especially with penicillin, reduces the chance of a syphilitic woman passing her infection on to her baby or to anyone else, in proportion to the adequacy of the treatment given. It should be remembered that a positive serological test for syphilis is not necessarily equivalent to a diagnosis of syphilis.

## Enuresis in Young Adults

**Q.**—Can anything be done to benefit chronic enuresis in young adults? In the case I have in mind full neurological and urological examinations have proved negative.

**A.**—This condition is almost certainly a psychological one. Drug treatment, such as the use of belladonna, may sometimes break a vicious circle in that the very suggestion of past failures makes for present and future ones, whereas a few nights of success might give greater confidence and start a new rhythm. But in the vast majority of cases the specific unconscious causes of the enuresis have to be discovered. The commonest are: (a) An unconscious desire to return to infancy, associated with a fear of going out into life, so that the patient unconsciously reverts to his infantile habit. (b) There is very commonly an infantile sensuous or sexual basis to the condition, for the infant finds pleasure in micturition, as in other excretory functions, and these, owing to repression, may be fixated and therefore arrested in development. These people often prove to be impotent or semi-impotent in adult life. (c) On the other hand, the enuresis may represent an unconscious rebellion, and the infant often uses this mode of making a nuisance of himself as a means of getting his own back on his nurse or mother: on account of the repression of their assertiveness such patients are commonly docile in character. Unfortunately, merely telling a patient the causes is not likely to help much, as they are repressed and will be denied, so that in most cases analytical treatment from a medical psychologist to discover the causes offers the only hope of cure.

## Tubercle Bacilli in Cheese

**Q.**—Are living tubercle bacilli present in cheese—that is to say, does the process of cheese-making destroy any tubercle bacilli which may be present in the milk?

**A.**—The answer to this question depends on whether the cheese (a) is made from raw or heat-treated milk, and (b) is stored long enough to enable any tubercle bacilli present in it

immediately after manufacture to die out. Generally speaking, tubercle bacilli in milk are destroyed by pasteurization, and tubercle bacilli in cheese die out within two months in storage at 50° F. (10° C.). At present about 90% of our cheese is imported. Most of this is made from pasteurized milk, and only a very small proportion of it comes on the market in under four months. The chief exceptions are Danish blue cheese and the soft Normandy cheeses of the Camembert type, both of which are made from raw milk. Danish blue cheese, however, is ripened for ten or twelve weeks, so that it should be relatively safe. Camembert, on the other hand, is only two weeks old at the time of export, and is marketed as rapidly as possible after arrival in this country, so that it must be regarded as potentially dangerous. Of the cheese made in Great Britain an increasing proportion of the Cheddar type is prepared from pasteurized milk, and little, if any, Cheddar cheese reaches the shops in under two months. Cheshire and Lancashire cheeses are usually made from raw milk, and may be sold within two weeks. It is probable, therefore, that they often contain living tubercle bacilli, particularly as they are now produced almost entirely in the North Midland region, where the incidence of tuberculosis in cows is higher than in any other part of the country. Soft cheeses made from salvaged milk, and eaten within a few days of manufacture, must also be frequently infected. There is no reliable information on the danger of eating cheese containing tubercle bacilli. Whatever the risk, it is probably considerably less than that of drinking raw milk, which not only contains greater numbers of tubercle bacilli but is generally consumed in larger quantities than cheese. (The subject of cheese-borne infection, with particular reference to typhoid fever, was dealt with in an annotation on page 730 of our issue of June 12, 1943.)

#### Induction of Labour

**Q.**—*What are the methods of choice for inducing labour in cases which are overdue, or in which it is desirable to induce labour two or three weeks early? Authorities seem to vary, and I should like to know the latest views.*

**A.**—Medical induction is preferable to surgical methods and, although it is rarely successful unless the patient is at or past term, should always be tried first except when there is urgency. Medical induction consists in the usual castor oil, enema, and hot bath; quinine should not be used if the foetus is alive. It is difficult to prove, but nearly all obstetricians believe that this drug is harmful to the child and may cause its death. Posterior pituitary extract, if used at all, should be given with caution and in the smallest doses; moreover, it is often contraindicated by the condition for which induction is necessary—for example, toxæmia of pregnancy or disproportion. When the foetus dies *in utero*, priming of the uterus with oestrogens for five to eight days before the medical induction is an advantage, but it is doubtful whether oestrogens have any significant effect when the foetus is alive.

Of the surgical methods, rupture of the forewaters is probably the most popular, but it should be carried out only when the cervix is already effaced and the presenting part is fitting well down into the pelvis. Some prefer to tap the hindwaters with a Drew-Smythe catheter. Stripping of the membranes from the lower uterine segment, either alone or preparatory to withdrawing liquor, is also a useful procedure. The use of bags, bougies, and tubes has been largely abandoned, and most obstetricians believe that no surgical method of induction should be practised when the foetus is dead. When the pregnancy is not ripe for induction—that is, when the presenting part is not engaged or the cervix is long and undilated—induction is best avoided.

#### Osteomyelitis of Femur

**Q.**—*What is the prognosis in adult cases in which osteomyelitis of the femur began in childhood? What is the correct treatment for a discharging sinus when x-ray examination shows no evidence of a sequestrum?*

**A.**—When chronic osteomyelitis follows an acute haematogenous attack the prognosis for permanent cure is notoriously uncertain, particularly if multiple "flares" of infection have occurred. Even after complete skin-healing and absence of

symptoms for many years there is always a risk of further recrudescence. Such exacerbations may sometimes be precipitated by deterioration of the general health, or by unaccustomed activity of the part, or by injury. In spite of the uncertainty of the long-term prognosis, however, it should as a rule be possible to clear up existing sinuses by appropriate treatment. This usually necessitates surgical exploration of the extent of the sinuses and eradication of their cause—most often a sequestrum or a persistent area of osteitis. The fact that sinuses persist indicates with certainty either one or both of these lesions, even if the radiographs are apparently negative. Surgical treatment on these lines should be supplemented by an adequate period of general rest, preferably in an open-air hospital, and by temporary immobilization of the affected part. Adequate doses of penicillin both during and after the operation increase substantially the prospects of cure; indeed, under penicillin control it has in many cases been possible, after removing all diseased bone, to obtain first-intention healing by primary suture of the skin. It is perhaps better, however, to leave the wound open for five to fourteen days and then undertake delayed primary suture or a skin graft.

#### Treatment of Sclerodermia

**Q.**—*Dihydratachysterol was reported to have given excellent results in sclerodermia (J. Amer. med. Ass., 1946, 130, 570). Has this claim been substantiated by further reports?*

**A.**—There is no certain treatment for sclerodermia. Psychogenic factors may be important. Gold therapy sometimes helps, as may x-ray therapy locally in small dosage. The reference cited is to a case of sclerodermia following thyroidectomy and probable removal of the parathyroids, so that there were special circumstances indicating the use of dihydratachysterol. The writer has not found help from the antihistamine preparations or calciferol. Recently the local application of promin jelly has been advocated in America (Wuerthele-Caspe, V., Brodtkin, E., and Mermod, C., *J. med. Soc. N.J.*, 1947, 44, 256).

#### Chilblain of the Nose

**Q.**—*Is there a remedy for chilblain of the nose? Except in the warmest weather my nose is very cold and inclined to be red. For the past five or six years, with the onset of cold weather, the end of the nose becomes swollen and shiny and a typical chilblain develops. I have tried prolonged courses of calcium lactate, vitamins, nicotinic acid, and short-wave diathermy without success. I am 74 and lead an active and busy life. I never before had a chilblain.*

**A.**—It is not common for chilblains to appear first at this late age; such an event suggests a degenerative change in the cutaneous vessels. The questioner has tried most of the accepted remedies without success, but iodine has been acclaimed by some. It should be prescribed as Lugol's iodine 5 drops twice daily, increasing the dose slowly to 60 drops in the day; it may be combined with dried thyroid, especially if the patient is over weight. Bathing the affected part with equal parts of hydrogen peroxide (15 vols.) and hot water for ten to fifteen minutes daily, followed by vigorous friction with a rubefacient such as methyl salicylate ointment, often gives relief. Artificial sunlight has been found by many to be a useful prophylactic.

#### Unequal Pupils and Fibrillatory Twitchings

**Q.**—*(a) What significance should be attached to unequal pupils in a candidate for life insurance?*

*(b) Do fibrillatory twitchings in muscles invariably indicate the onset of a neuropathic muscular atrophy? I have two patients who exhibit this phenomenon in the calf muscles following high ligation of the saphenous veins.*

**A.**—*(a)* Unequal pupils in themselves do not debar a candidate from life insurance. A consistent pupillary inequality should, however, call for special clinical vigilance on the part of the examining medical officer. He should, to begin with, determine which of the pupils is the "normal" one—that is, whether the smaller pupil is forming part of the syndrome of an oculo-sympathetic paralysis. X-ray examination of the neck and chest, a blood Wassermann test, and an examination of

family doctor, the hospital at which he should be treated, and free to decide whether he avails himself of the public service or obtains the medical service he needs independently.

IV. Doctors should, like other workers, be free to choose the form, place, and type of work they prefer without governmental or other direction.

V. Every registered medical practitioner should be entitled as a right to participate in the public service.

VI. The hospital service should be planned over natural hospital areas centred on universities in order that these centres of education and research may influence the whole service.

VII. There should be adequate representation of the medical profession on all administrative bodies associated with the new service in order that doctors may make their contribution to the efficiency of the service.

6. In this memorandum the Committee concentrates on those aspects of the Government's scheme which appear to it to need modification. There are others which are commended or accepted by the profession, including the principle that the service should be available to the whole community, the proposed planning and development of hospital services on regional lines and the general structure of local executive councils.

[NOTE.—In general, the principles of the Negotiating Committee's case are applicable to the Scottish Act as well as to the Act for England and Wales, with the Secretary of State taking the place of the Minister.]

### GENERAL PRACTICE

7. The two features of Part IV of the Act which have aroused the gravest misgivings of the medical profession are the abolition of the custom of buying and selling general practices and the establishment of a machinery of "negative direction" over the movements of general practitioners. In its published comment on these features of the Act, issued by the Negotiating Committee in November, 1946, the following statement appeared:

"The Act provides for the abolition of the custom of buying and selling general practices and for the establishment of a machinery of negative direction over the movement of general practitioners, while the profession maintains that the ownership of goodwill is essential to the continued freedom of the general practitioner. This abolition is regarded as a first and substantial step to a State salaried service, while the system of 'negative direction' which is proposed is an unjustifiable and unnecessary interference with the freedom of the doctor. Any necessary improvement in the distribution of doctors can be achieved on the existing basis of general practice.

"The abolition of the custom of buying and selling practices creates more problems than it solves."

### DISTRIBUTION

8. The question of distribution of the profession is taken first because it is upon the need for better distribution that the Minister based his arguments for the abolition of the ownership of goodwill in public general practice.

Problems of distribution can be met in a satisfactory way by dealing with any cases of under-doctoring as they actually exist or occur. No areas will remain under-doctored because of inability to purchase medical service, for, as a result of the Act, there will be available a medical payment in respect of every member of the community. The medical payment will be the same in respect of every patient, wherever he lives and whatever his status. Doctor-distribution in relation to population-distribution will follow naturally upon a 100% service. When stability has been reached any remaining deficiency in medical man-power

in particular localities can be effectively remedied by adjusting the terms and conditions of service so as to attract to the under-doctored area the medical practitioners who are needed, even to the extent of an appointment by the Minister of a doctor on special terms.

The discontinuance of the traditional methods of transfer of and succession to practices creates fresh problems of distribution.

9. The Act provides that every practitioner seeking to enter general practice in the public service in any area after the appointed day must first obtain the permission of the Medical Practices Committee, and, as is shown subsequently, in no case will the granting of this permission be a mere formality. An examination of the procedure proposed demonstrates that it will be a cumbersome and slow-moving business. An illustration of this is afforded by the course of events on the occurrence of a doctor's death. The Local Executive Council, being informed of this event, must first report to the Medical Practices Committee on the necessity of filling the vacancy. The Medical Practices Committee will need local knowledge before it can determine this issue. Neither in these nor in any other circumstances will the Medical Practices Committee be able to rely on overall figures for general practitioners and population in the area, for the experience of the Central Medical War Committee proves that the over-doctored area contains under-doctored patches and the under-doctored area contains over-doctored patches. It is no help to a patient of the deceased doctor to explain that, in the county as a whole, there are sufficient medical practitioners. The Medical Practices Committee must examine the report of the local committee before it decides whether or not to fill the vacancy.

Let it be assumed that it is decided to fill the vacancy. Presumably the Local Executive Council or the Medical Practices Committee will advertise and candidates will duly apply. It will fall to the Local Executive Council, in consultation with the Local Medical Committee, to examine the applications, to interview the candidates, and to arrive at a short list for recommendation to the Medical Practices Committee. In due course the Medical Practices Committee, presumably after interviewing the short-listed candidates, will reach a decision. This done, the unsuccessful candidates may appeal to the Minister against the decision. Such appeals having been considered, the final decision will be reached and a doctor will be chosen to fill the vacancy.

10. But what has happened in the meantime? At a conservative estimate, the procedure outlined above will have taken some three or four months. In the meantime the Local Executive Council is responsible for securing medical care for the patients of the deceased practitioner. The Council may ask the neighbouring practitioners to undertake the work. If they agree, it is probable that after three or four months many of the patients of the deceased practitioner will have transferred to the lists of the neighbouring practitioners, leaving little practice for the appointee on arrival.

On the other hand, the neighbouring practitioners may not agree to undertake the work, or their lists may be so heavily burdened that they cannot undertake extra work, and the Council may appoint a locum. After three to four months the locum may be generally accepted by the patients of the practice. The widow may have sold the house to him (or she may have sold it to another doctor or to a layman). It is difficult to see how the Medical Practices Committee could make yet another change and bring in a fresh practitioner.

## A Pleasant Food Supplement for Motherhood

... which is invaluable to nursing and expectant mothers. A specially balanced food of cocoa, malt extract and sugar, Vivomin contains the vitamins and minerals essential for the maintenance of good health during pregnancy and lactation. For expectant mothers we recommend 1 teaspoonful and for nursing mothers 2 teaspoonfuls, which, when mixed with hot or cold milk, makes an extremely palatable beverage.

Vivomin contains in each teaspoonful:

Vitamins.	Milligrams	Minerals.	Milligrams
Vitamin B <sub>1</sub>	0.34	Calcium	340.0
Vitamin B <sub>2</sub>	0.34	Phosphorus	175.0
Vitamin C	34.0	Iron	5.8
Nicotinic Acid	3.4	Copper	0.34
		Manganese	0.34
		Iodine	0.115

# VIVOMIN

4/- per 4-oz. tin (retail price)

THE CROOKES LABORATORIES LIMITED  
PARK ROYAL, LONDON N.W.10

## NOW AVAILABLE "DIHYDROERGOTAMINE -SANDOZ"

(LABORATORY NUMBER D.H.E. 45)

AN IMPROVED SYMPATHETIC  
SEDATIVE WITH NO ACTION  
ON THE UTERUS

This new semi-synthetic alkaloid possesses a similar action to ergotamine in migraine and in sympathicotomies. The toxicity of the new alkaloid is reduced, the constrictory action on the uterus and vessels is absent and the sympathicolytic activity is enhanced.

SUPPLIED IN—

Ampoules 1 c.c. (1 mg.); Boxes of 3, 6, 50 and 100.

Oral Solution (0.2%); Bottles of 15 c.c.

(The oral solution is so far in limited supply.)

SANDOZ PRODUCTS LTD.,  
134 WIGMORE STREET, LONDON, W.1

in two absorbencies  
**TAMPAX**

In 1934 saw the first adaptation of the principle of the surgical tampon to the absorption of the menstrual flow. Designed by a gynaecologist, Tampax not only gained the approval of the medical profession for its guarantee of hygiene and safety—the latter ensured by the patent stitching process which makes disintegration impossible—but won favour with women themselves for its alleviation of mental stress and physical discomfort.

Today, Tampax is recognised throughout the world as the most efficient form of sanitary protection, and is now available in two absorbency sizes. The introduction of Super Absorbent Tampax No. 2 has been widely welcomed by members of the medical profession who have stressed the need of a product to cater for a wider range of absorbency requirements. Of particular value to parous women, Super Absorbent Tampax No. 2—40% more absorbent—makes available to many thousands more women the complete freedom, comfort and hygiene of which the name of Tampax is symbolic.

Tampax may occasionally be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated where size of the vaginal aperture would cause difficulty in insertion and withdrawal.

Written 90 years

ago, his words

have never

been superseded

It was in 1855 that pernicious anaemia was first described by Addison. So accurate and detailed were his observations that they are still unexcelled as a description of the clinical picture.

Little progress was made in the treatment of anaemias, however, until the comparatively recent discovery of the curative effects of liver. To-day the value of liver extracts is well known.

Hepastab Forte is a concentrated extract of liver which has been produced in Boots' laboratories after extensive experimental work. Its high purity excludes all risk of undesirable reactions following administration, and it is painless on injection.

Hepastab Forte is indicated in cases of pernicious anaemia and other megalocytic anaemias. If desired, it may be given intravenously, but this is seldom necessary.

One cubic centimetre is therapeutically equivalent to 4,000 to 5,000 gm. of fresh liver by the mouth. Available in single ampoules of 1 c.c., also in boxes of 3, 6 and 12 ampoules.

## After Debilitating Illness

Allenburys Beef Juice is particularly suitable for administration in convalescence after severe and debilitating illnesses. It is not merely a stimulant but contains, in palatable and concentrated form, the nutritious and stimulant constituents of fresh, raw, beef juice, including albumen which is conserved by the process of manufacture *in vacuo* at a low temperature. Allenburys Beef Juice provides an easily administered, highly beneficial supplement to the diet.

In bottles at 3/- and 5/8 each.

*Allenburys*  
**BEEF JUICE**

ALLEN & HANBURY LTD. LONDON, E.2

## Ribena therapy for the anaemias

That the presence of vitamin C plays an important part in the utilisation of iron by the body and that deficiency of vitamin C in the dietary may produce anaemia, is now well established. In the treatment of iron-deficiency anaemias, therefore, an optimal intake of vitamin C is important for effecting complete recovery.

It has been reported that certain cases of pernicious anaemia, resistant to liver therapy alone, have responded when vitamin C was added.

These facts point to the advisability of providing an ample intake of vitamin C in the treatment of anaemia generally.

Ribena Blackcurrant Syrup is not only a rich source of the vitamin (not less than 20 mg. per fluid ounce); it also contains the associated factors of vitamin C in its natural form.

BLACKCURRANT SYRUP

H. W. CARTER & CO. LTD., THE OLD REFINERY, BRISTOL 2

11. Many of these difficulties arise from the fact that from the moment of her husband's death the widow has no interest in the practice as such and owing to the cumbersome machinery neither the Local Executive Council nor the Medical Practices Committee can effectively replace her in this respect.

12. Examples could be multiplied of the difficulties which will arise. Sons will join fathers only with the permission of the Medical Practices Committee. The final decision as to whether the incomer shall be male or female, young or old, British or alien, lies with a committee remote from the area. The burden of work falling on the Medical Practices Committee will be intolerably heavy. For in every case which comes before its notice there will need to be inquiry into the circumstances of the particular area in order to determine whether or not there is a sufficiency of doctors in it. This is a burden which no committee can discharge efficiently. The average number of additions to the medical register during the last five years is nearly 3,000 a year, and the removals from the register on death, etc., during the same period average 1,100 a year.

In an area, or part of an area, covered by say two doctors the Medical Practices Committee may decide that a vacancy arising from the death or retirement of one need not be filled. The effect would be to compel the patients of the vacant practice to secure their medical attention from the practitioner remaining in the area—who is not the practitioner of their choice, but the practitioner from whom those patients have chosen not to obtain their medical service.

13. There is another feature of the Act which contravenes the fundamental principle that the citizen should be free to choose or change his family doctor. Section 34 (4) empowers the Medical Practices Committee to grant an application to practise "subject to conditions excluding the provision of general medical services by the applicant in such part or parts of the area of the Executive Council as the Committee may specify." To restrict a doctor's practice, for example, to a particular part of a town is to deny his services to patients who may wish to obtain them and to compel those patients to seek treatment not from the doctor of their choice but from some other practitioner. This objection applies whether an area is held to be under-doctored or over-doctored. The present arrangement, which has worked satisfactorily over many years, gives discretion to an insurance practitioner to accept any person on his list whether or not the person lives within the area ordinarily covered by the doctor's practice.

### OWNERSHIP OF GOODWILL

14. In the discussions which have taken place between the Minister's representatives and the Committee, the Committee's original statement that "the abolition of the custom of buying and selling practices creates more problems than it solves" has been abundantly justified. Some examples of the problems created are given below.

#### Existing Partnership Agreements

15. Practically every existing partnership is governed by an agreement. In general, these agreements provide that in certain circumstances—e.g., the retirement, death, or sickness of one partner—the other partner, or partners, shall have an option, and often an obligation, to purchase the share of the partner retiring or dying.

16. So far as these partnership agreements are concerned the interpretation which the Ministry places on Section 35 of the Act on the advice of its legal advisers is:

"(a) Existing partnerships between doctors are not determined on the appointed day, nor is there any reason for partners to determine existing agreements. The position is the same whether all or only of the partners in a partnership join the new service.

(b) Clauses relating to the sale and purchase between partners of shares in the goodwill of the practice or the option to purchase such shares contained in a partnership agreement entered into before the appointed day will be unaffected by Part IV of the Act coming into operation on the appointed day and will remain operative. An obligation in such an agreement by a partner who joins the new service to buy from or sell to another partner a share in the practice, or the right of such a partner to exercise an option to buy or sell a share, either on a fixed day or the happening of an event after the appointed day, will continue as a right or liability of the partner concerned. No such sale would constitute an offence under Section 35 (2) of the Act.

(c) A doctor who is a member of a partnership and who joins the new service will lose the right to sell his existing share in the partnership, except to an existing partner in pursuance of the partnership agreement. While the various rights (whether in the form of options or obligations) to buy a further share in the partnership which exist under the typical partnership agreement will continue he will not be able to sell those rights. All these matters will have to be taken into consideration in fixing as between partners their respective shares of the compensation attributable to the partnership practice, and provision for this will be made in the Regulations under Section 36 (3)."

17. This official interpretation means that all partnership agreements in existence on the appointed day retain their full validity. Is the Ministry interpretation right? This was the question the Negotiating Committee submitted to an eminent Chancery counsel, who found himself able to express an opinion, to use his own words, only "after long suspense of judgment and fluctuations of view." His first conclusion was that on balance (he regarded it as a "fifty-fifty" affair) the Ministry interpretation should prevail. His opinions have been conveyed to the Ministry. What follows in paragraphs 18-27 is on the assumption that the Ministry interpretation of Sections 35 and 36 is right.

18. Acceptance of the Ministry's interpretation, however, gives rise to two main difficulties: (a) It is impossible to determine, in advance of the various contingencies which may arise under the usual partnership deed, the amount of compensation "payable to any medical practitioner." Even if it be assumed that the amount of compensation due to a partnership can be calculated it is impossible to calculate the shares of individual partners. (b) It is impossible to determine at the appointed day how and to whom interest due on the compensation moneys should be paid.

19. It is necessary to examine some implications of the Section, on the Ministry's interpretation. Where practitioners A and B are bound by a partnership deed which contains the usual mutual options or obligations to buy the share of a retiring or deceased partner, the compensation due to each partner *cannot be determined until it is known who dies or retires first*. It is impossible to assess in advance the cash value of the various options and liabilities. The amount of compensation due to a practice can be estimated, but in the case of a partnership the division of the amount of compensation is impossible until certain events have in fact happened. In the meantime it will not be known in what proportions to divide between the partners the interest which the Government has promised to pay between the appointed day and the liquidation of the compensation sum.

20. It has been suggested that this difficulty could be overcome where both (or all) members of a partnership enter the new service: (a) by regarding the partnership as one practice for the purpose of calculating compensation; and (b) by arranging, when subsequent transfers of shares are made between the partners, for the compensation to "follow the share." Thus where a continuing partner A is required to buy the share of his retiring partner B (in, say, five years' time) the compensation apportioned to B's share will be transferred to A. Having received A's purchase money, B would have suffered no loss by reason of being unable to sell his share in the practice and would not, therefore, be entitled to compensation under the Act. A, who cannot resell, has suffered the whole of the loss sustained by the partnership and would receive the whole of the compensation. C, whom A brings into the practice to help him in B's place, will lose nothing, because he will pay nothing on entering the practice.

21. There are at least two objections:—(a) Though compensation may "follow" a share of the practice when it is sold, such compensation may or may not be equal to the sum paid by the purchaser for something which he cannot subsequently sell. A practitioner buys something at one price, but its value, when he comes to be paid the compensation due, may be a lower or a higher price—probably a lower price. (b) The Act requires that interest should be paid annually from the appointed day until the time when the compensation sum is paid. Under Section 36 (3) (d) the interest is to be paid "on the compensation payable to any medical practitioner"—that is, to the practitioner entitled to the compensation. If interest were apportioned and paid on the basis of the partnership shares as they exist on the appointed day, a partner who in, say, five years' time fulfils an obligation to buy an additional share in the partnership would lose the interest paid over those five years on the compensation due in respect of that share of the partnership. On the other hand, the seller would have received during those five years the interest in a compensation sum to which he is not entitled, in so far as the Act has not prejudiced his right to sell and, in fact, has not precluded him from selling. He will have received interest on a compensation sum which is going to be paid, not to himself, but to the man who has bought him out. In brief, the buyer has bought something which the Act precludes him from selling but has lost some of the interest on the compensation which the Act provides in respect of that prohibition. The seller has received interest on a capital sum to which he is not entitled.

22. The Ministry contends that the position is the same whether all or any of the partners join the new service. This is inaccurate. For example:

(i) Consider the case of practitioners A and B in partnership, with B under an obligation to purchase A's share on A's death or retirement. Assume that A enters the service, but B does not. The medical profession has been promised that its members will be free to enter or not to enter the service. B, exercising this right, decides not to enter the service. In due course A retires and B is required to purchase his share. B, having no alternative, purchases A's share, only to find that he cannot enjoy the income from the public general practice which he has purchased without entering the service. But on entering the service he forfeits the right to dispose of both his own share and the share he has just purchased from A. He sacrifices these rights without compensation, for there can be no compensation to a practitioner who joins the service after the appointed day. The Committee does not believe that Parliament contemplated that the Act would have this effect of expropriation. It may be that the practitioner desiring to remain outside the service will in self-protection be forced into the service. This would be a breach of the promise given

during the second reading of the Bill that the profession is free to enter or not to enter the service—viz.: "The Bill places no obligation on any medical practitioner. He may stay outside the service altogether if he wishes to do so." (*Hansard*, May 1, 1946, col. 220.) The Committee asks the Minister whether he proposes to leave the position where it is.

(ii) Another situation arises if B retires or dies first and A is required to purchase B's share. Having done so, A is precluded from disposing of that share because he is a member of the service. Having joined the service on the appointed day he is entitled to compensation in respect of his own share of the practice, but he is left bound to buy a share which he cannot sell and for which there is no compensation. The Minister's representatives have stated that they are advised it is lawful to give compensation to a practitioner in partnership not merely in respect of the share he holds on the appointed day but in respect of a further share which he subsequently lawfully acquires in pursuance of the partnership agreement. On the contrary, the Committee is advised that the Act provides for compensation only in respect of the goodwill a practitioner owns on the appointed day. But even if the Minister's advisers are correct, there is no element in the global sum of £66,000,000, or the "appropriate proportion" thereof, for this compensation; for this amount will, under the Act, be calculated in proportion to the number of practitioners who actually join the service on or before the appointed day. Compensation in respect of a share purchased from a partner outside the service could be provided from the global sum only at the expense of the practitioners within the service. To provide fresh money would involve new legislation.

23. There is a further complication of a technical character. £66,000,000, or some proportion of it, is the global sum for compensation purposes. Hitherto it has been contemplated that, when all the claims have been made, steps will be taken to calculate the amount of compensation due in respect of each practice brought into the service. This is on the assumption that the whole of the global sum is to be distributed. But the effect of the Act is to leave an undistributable residue in the compensation fund. The Act requires that there shall be paid out in compensation the sum of £66,000,000 or an appropriate proportion thereof, this proportion being calculated on a formula laid down in the Act relating the amount to the number of practitioners who do in fact enter the service. For an amount of money to remain undistributed would be in conflict with Section 36 (2) of the Act. For example, if practitioner A, being in the service, is bought out under an existing agreement by practitioner B, not in the service, practitioner A, having been paid in full, loses his claim on the compensation fund. The amount which, on the appointed day, was set aside for his compensation can no longer go to him or to anyone else—and interest on this amount will have been improperly paid. It is impossible to calculate in advance what the size of this residue will be. Accordingly, it is impossible finally to calculate the amount to be allocated to any individual practitioner in compensation until the death or retirement of the last practitioner in partnership who joins the service. Being unable to calculate the amounts of compensation, the Government is unable to calculate the appropriate amounts of interest which it is required to pay each year to individual practitioners.

24. Furthermore, if every principal entered the service, either of his own free will or because of this pressure of the Act, the number of principals would be in excess of the figure of 17,900 used in the calculation of the £66,000,000. The Government's advisers calculated this number, it will be recalled, on the assumption that some principals remained outside the service. If every principal entered the service the sum of £66,000,000 would, apart from all other considerations, be inadequate for their compensation.

25. The Negotiating Committee has been promised that wherever a principal entering the service on the appointed day can demonstrate that he has suffered hardship in respect of a debt incurred in the purchase of his practice he will receive immediate payment of the compensation to which he is entitled. It will be impossible to give effect to this promise because, for reasons already adduced, it is impossible accurately to assess at the appointed day the amounts of compensation due either to individual practices or to individual practitioners.

26. To sum up, the consequences of the Ministry interpretation of Sections 35 and 36 of the Act in their present form include:

(i) Existing agreements, with all their options and liabilities, financial and other, remain legally valid despite the fact that they were designed to meet entirely different circumstances.

(ii) As a result, an individual practitioner may be required to pay out a sum of money to purchase a share the compensation value of which is less than the amount he has paid.

(iii) As it is impossible to estimate in terms of money the various rights, obligations, and options in typical partnership agreements, it is also impossible to estimate at the appointed day the shares due to individual partners. This being so, it is impossible to carry out the requirement of the Act that interest should be paid annually to individual practitioners.

(iv) In fulfilling his contractual obligations under a partnership deed a practitioner may be required (a) to buy a partner's public practice, the capital value of which he cannot realize, the income from which he cannot receive, and compensation for which is not available to him; or (b) to buy a partner's private practice, which he cannot sell and in respect of which no compensation is payable from the moneys provided under the Act.

(v) It appears likely that the assumption hitherto made that it will be possible to estimate the shares of individual practices (as distinct from individual practitioners) is unfounded, as the Act requires, in theory, that the whole of the £65,000,000, or the appropriate proportion thereof, shall be paid out, and in practice there will be an undistributable residue. The Government cannot keep its promise in regard to the relief of hardship and at the same time put into operation the Act in its present form.

(vi) In the Committee's view Sections 35 and 36 of the Act in their present form are unworkable. The official interpretation is doubtful because of the ambiguity of the phraseology used, and even if it be accepted unfairness amounting in some cases to expropriation will result.

27. The preceding paragraphs have been written on the assumption that the Ministry interpretation of Section 35 in relation to pre-existing partnership deeds is correct. The doubts expressed on this point by Chancery counsel of the highest eminence have already been mentioned. Counsel has used these words: "I still have very grave doubts as to the true construction of Section 35, which, unless made clear, will in my opinion reflect no credit on its authors." Because of the obvious doubts in the mind of counsel, a further legal opinion was sought jointly from Sir Cyril Radcliffe, K.C., and Mr. J. H. Stamp. After the fullest consideration, they have both reached the conclusion that the Ministry interpretation of Sections 35 and 36 is wrong. Their reasoned opinion will be conveyed to the Ministry as soon as it is received.<sup>1</sup>

It is submitted that a grave injustice would be done if this situation is allowed to remain. An authoritative opinion can only be given by the House of Lords, and while it is recognized that this is true of any legislation the essential feature in this case is that it is known now that ambiguity exists, giving rise to the situation that no medical practitioner, even after consulting his solicitor and

counsel, can be certain of his position. Moreover, the question can only be brought before the House of Lords at the expense of some individual medical practitioners in an action at law. Setting aside the arguments which have been raised earlier in this memorandum as to the inequity flowing from the Ministry interpretation, it is strongly urged that in any case the Act should be amended to remove the ambiguities.

Indeed, individual members of the medical profession have a right to know before the appointed day how the Act will affect them. It is unjust to leave a demonstrably ambiguous Act unamended and their own financial position uncertain until a case has been fought out in the Courts. Doctors who do not join the service by the appointed day will not qualify for compensation. For this reason alone they need to have the position precisely defined at least six months before the appointed day.

They must know beyond all reasonable doubt whether existing partnership agreements remain in force or not. The Ministry says they do and the highest legal opinion available says they do not. Where do partners stand? Are all existing agreements rendered null and void, with all the consequences which flow from such an extraordinary position?

The Act has nothing to say about the validity, after the appointed day, of existing partnership agreements. If learned counsel are right, a practitioner who, being bound by an existing agreement to buy or sell a share, carries out his obligation will be liable to fine or imprisonment, or both. Such a situation is intolerable.

#### Partnerships after the Appointed Day

28. In partnerships formed after the appointed day between practitioners involving a practice in the public service it will be illegal for the partners to distribute the emoluments of the practice except in the proportion in which they are earned. In the terminology of the Act there is deemed to have been a sale of goodwill "where in pursuance of any partnership agreement between medical practitioners services are performed by any partner for a consideration substantially less than those services might reasonably have been expected to be worth having regard to the circumstances at the time when the agreement was made."

Even if the argument be admitted—and it is based on no more than a Ministry interpretation of the Act—that the "worth" of a partner could be assessed not only on services rendered but also on his seniority and experience, it is impossible to assess what the experience of the senior partner "might reasonably have been expected to have been worth." It is equally difficult to assess the anticipated value of the services of a junior partner at the time when the agreement is made. In any case, the respective "values" of junior and senior partners may change materially over the years. The general effect will be to discourage senior partners from taking junior partners. It illustrates that the Act seeks to destroy the indestructible, for, whatever legislation may be passed, the successful practitioner possesses something of value in the goodwill of his practice.

29. It is ironical that an Act which purports to encourage the development of group practice should in its operation have precisely the opposite effect—that of discouraging practitioners from entering into partnership one with another, whether inside or outside health centres.

30. It is a curious and presumably unforeseen anomaly arising from the Ministry interpretation that, should practitioners after the appointed day but before their entry into

<sup>1</sup>This opinion has now been conveyed to the Ministry, and appears at p. 151.

the service enter into a partnership deed involving buying or selling, that deed will still be binding on the participating practitioners.

### Assistants

31. It is highly desirable that newly qualified practitioners seeking to enter the field of general practice should, for a period, act as assistants to practitioners whose names are on the lists of Executive Councils, so as to gain the necessary experience. A practitioner who employs an assistant at remuneration "substantially less than his services might reasonably have been expected to be worth having regard to the circumstances at the time when the remuneration was fixed" and who subsequently admits the assistant to partnership commits an offence. The effect of this will be to discourage practitioners from admitting assistants to partnerships and to encourage them to employ assistants for short terms without the prospect or possibility of partnership. Add to this the diminished incentive to become an assistant because by application one may succeed in acquiring an independent practice and it appears the prospect of there being sufficient assistants will become remote. The effect will be that more and more practices will be left with no one in charge when a principal dies or retires.

### The Doctor's House

32. The widow of a practitioner who has worked in the service is precluded from selling the house to another practitioner with the knowledge that it will be used for practice purposes, if the purchase price is "substantially in excess" of the price which might reasonably have been expected if the premises had not previously been used for practice purposes.

The effect of this may be, first, to penalize the widow by leading her to accept a price which is less than the real value of her property; secondly, to run the risk of prosecution by putting up the house for auction; or, thirdly, to lead her to sell to a third party who will offer it at a higher price to the incoming practitioner; or, fourthly, she may sell it outside the medical field entirely, so making medical practice in the area more difficult.

Many premises have been adapted structurally for professional use, and in these cases it will be impossible to assess the price "which might reasonably have been expected if the premises had not previously been used for practice purposes."

33. It may be argued that the system of registration of agreements with the Medical Practices Committee will protect the profession and the public from the dangers referred to in the foregoing paragraphs, although it is difficult to see how the widow could be afforded protection. But nothing is now known, or can yet be known, by the Ministry or the profession, of the attitude which may be adopted by any Medical Practices Committee. Such a committee will have no alternative but to interpret the sections of the Act as passed by Parliament. However much it may desire to do nothing to endanger partnerships and assistantships or to endanger practitioners, it cannot act except in conformity with the definitions set out in the Statute.

### Remuneration

34. The Committee asks that the Minister will now make clear his attitude on the subject of remuneration. The subject is not dealt with in the Act. The Committee is aware of the Minister's acceptance in principle of the majority recommendations of the Spens Committee. It would now be grateful for the Minister's views on the

translation of those recommendations into terms of actual remuneration. It is the Committee's view that, except where special circumstances justify it, the remuneration of general practitioners should be by capitation payment in proportion to the number of persons on a doctor's list, and that this principle, which it regards as fundamental, should be embodied in the Act. It is opposed to the payment generally of a salary, basic or other, considering that in ordinary circumstances the general practitioner should be paid by capitation fee. The time has now come for a clear and detailed statement on the whole subject. The Minister will recall the statement of the Lord Chancellor in the House of Lords on Oct. 28, 1946, replying to an argument that the terms and conditions of service should be made known to the profession well before the appointed day, that "the Minister agrees that we ought to aim at a period of six months so that the doctors can have ample time to make up their minds as to whether they are going to come in or not."

### Right of Appeal to the Courts

35. The view is widely held in the medical profession that there should be a right of appeal by the practitioner affected to the Courts of Law from any decision of the tribunal to remove a practitioner's name from the lists of any or all Executive Councils, or, alternatively, that there should be a right of appeal from any adverse decision of the Minister on this point. In the Health Service Bill for Northern Ireland a practitioner aggrieved by any decision of the tribunal is given the right of appeal to the Supreme Court.

36. As the Seventh Schedule now stands the medical member of the tribunal will act in all cases in which the case of a medical practitioner is considered by that body. Only if he is unable to act will it be possible for the Minister to appoint a deputy. This position is unsatisfactory. It is highly desirable that the case of an individual medical practitioner should be adjudicated upon by a tribunal containing a practitioner familiar with the type of practice and the type of area from which he comes. An amendment of the Schedule would be necessary to make this possible.

### Midwifery

37. The criteria for the statutory qualifications to practise medicine, surgery, and midwifery are similar in England and Wales, in Scotland, and in Northern Ireland. The right to participate in the midwifery service provided as part of the National Health Service in Scotland and Northern Ireland is accorded to all practitioners by virtue of their statutory medical qualification, but in England and Wales the Minister has taken power to restrict that right by imposing a qualification additional to the statutory qualification. This is inconsistent, unnecessary, and undesirable.

### OTHER POINTS

#### Chairmanship of Local Executive Council

38. This body should enjoy the right of appointing its own chairman from among its own members—professional or lay—or from outside, just as insurance committees appoint their own chairmen to-day. Even if it is accepted as a matter of convenience that the Minister should appoint the chairman for a preliminary period, there is no case for continuing to deprive the committee of the right to appoint its own chairman. Any such preliminary period should be of short duration. To effect this change amendment of the Act is necessary.

### Consultation with Local Units of the Profession

39. So far as general medical, dental, and pharmaceutical services are concerned, the responsible local body—namely, the Executive Council—in exercising its functions under Part IV of the Act, is required to consult with local committees representative of the professions concerned. The Act does not impose a corresponding measure of consultation in the case of the Regional Boards and the Local Health Authorities. The Regional Hospital Board, in preparing its scheme for the local administration of hospital and specialist services, is not required by the Act to consult the local medical profession. The Local Health Authority, in preparing its scheme for carrying out the duties imposed by Part III of the Act, is not required by the Act to consult the local medical profession, though it is required to send a copy of its proposals to the Regional Hospital Board, the Governors of any teaching hospital in the area, the Executive Council, other Local Authorities in the area, and “to every voluntary organization which to the knowledge of the Local Health Authority provides in the area of the Authority services of the kind dealt with in the proposals.” This means, for example, that the Body which is charged with the duty of providing, equipping, and maintaining Health Centres where, *inter alia*, general medical services will be provided is not required to consult the local medical profession by whom these services will be provided. Such consultations should be provided for as a requirement in the Act.

The local executive council is not required to consult the local medical committee in all appropriate matters coming before it but only “on such occasions and to such extent as may be prescribed.” This limitation is regarded as unsatisfactory.

### Scope and Conditions of Service

40. (a) In general, and subject to what is recommended below, the definition of the scope of the general practitioner service should follow the lines of the existing definition of the obligations under the National Health Insurance Act.

#### Anaesthetics

(b) The administration of anaesthetics in midwifery and dental cases should be excluded from the practitioner's obligations.

(c) The administration of other anaesthetics for patients on the list of the practitioner concerned should be within the terms of service only if: (1) the operation is of a kind which is usually performed by, and is in fact performed by, a general medical practitioner, and (2) the administration of the anaesthetic or the other assistance rendered does not involve a degree of special skill or experience not possessed by general practitioners as a class.

#### Emergency Attendances

(d) The following procedure should govern emergency attendances:

A. *Public Service Patients on Practitioners' Lists*.—(i) That a public service practitioner should be under an obligation to make deputizing arrangements to the satisfaction of the Executive Council and the Local Medical Committee.

(ii) That in an emergency the public service practitioner could properly be under an obligation to attend a public service patient not on his list; where the patient has tried unsuccessfully to obtain the services of his own doctor or his deputy, or where the doctor is satisfied that such is the grave nature of the emergency that the calling in of the nearest available doctor is justified.

B. *Patients Not on Practitioners' Lists*.—Where emergency treatment is rendered to a patient whose name is not on the list of any practitioner in the service: (i) The patient may, if he so desires and if he is resident in the area of the doctor's practice, ask to have his name included in the list of the practitioner rendering the treatment. Where the patient does not reside in the area of the practice he may express a desire to be treated as a public service patient. In the circumstances here indicated no fee should be payable by the patient for the emergency treatment. (ii) The patient may, if he so desires, elect to be treated as a private patient.

C. *Practitioner's Fee for Attendance in Emergencies*.—Where a public service practitioner attends in an emergency he should be entitled, on making application, to a fee from the service for his attendance.

#### Practitioners' Lists

(e) (i) A practitioner entering the service should retain his present National Health Insurance list. (ii) The objective should be a maximum of 4,000 public patients per practitioner.

#### Certification

(f) The requirement is imposed by Section 33 (2) (d) of the Act to issue certificates “for the purposes of any enactment,” which includes the purposes of regulations made under any enactment. The Committee's view is that the practitioner's obligation should be limited to certificates under the National Health Service and the National Insurance Acts, 1946. Although it welcomes the establishment of a committee to examine the whole position of certification, the burden of certification is bound to be oppressive while Section 33 (2) (d) of the Act remains in its present form.

#### Health Centres

(g) (i) The Central Health Services Council should appoint a Standing Advisory Committee on Health Centres; the establishment of these Centres should proceed experimentally and under central control. (ii) No practitioner should be compelled to undertake service at a Health Centre. (iii) The Medical Committee of the Centre, including its chairman, should have an appropriate status in relation to (a) the administrative arrangements of the Centre, and (b) the making of appointments of persons—e.g., nurses—employed at the Centre. In general, the responsibility for the arrangements at the Centre so far as these relate to general medical services should rest with the Medical Committee.

#### Assistants

(h) (i) It is highly desirable that newly qualified practitioners seeking to enter the field of general practice should, for a period, act as assistants to practitioners whose names are on the lists of Executive Councils so as to gain the necessary experience. (ii) There should be no legal requirement to prohibit a newly qualified practitioner from having his name included, for the purposes of independent practice, on such lists. (iii) It should be permissible for an agreement to be required by a principal from an assistant which would prohibit him, on leaving the practice of the principal, from having his name entered on the local list in competition with the practitioner for whom he has been working.

#### Collective Responsibility

41. On and after the appointed day a proportion of the population will sign on doctors' lists. Of the remainder, a proportion, varying in different areas, will sign on doctors' lists when the need arises to consult a doctor. A third group will consist of persons who do not intend to use the service and adhere to their intentions.

The Committee has considered the possibility of limiting the obligation of public service practitioners to those persons who have in fact signed on doctors' lists. It soon became obvious that it would be impossible so to limit this obligation, bearing in mind that at any time, including the beginning of an illness, an individual may decide to use the service.

Thus an obligation will exist to attend two of the three groups described above, those who have in fact signed on doctors' lists and those who will at some future date. Indeed, as any member of the community can at any time call a doctor, and at the outset of the consultation request to be accepted as a public service patient, there does exist a responsibility relating to the whole community. In any case, it is clear that for the first two groups that responsibility will exist from the beginning.

With this in mind, collective responsibility for the great majority of the community will exist and it is essential that this should find expression in a central fund, made up of the total number of persons estimated to be at risk multiplied by the agreed capitation fee. The two things necessarily go together—collective responsibility and a central fund.

There should be established a central practitioners' fund equal to the capitation fee agreed upon multiplied by a number equal to a high percentage of the population; this percentage being less but only slightly less than 100. The allocation of the central practitioners' fund would be the responsibility of a Distribution Committee analogous to the one now in existence for the purposes of National Health Insurance.

## HOSPITAL AND SPECIALIST SERVICES

### Transfer of Hospitals

42. In its present form the Act makes possible a State monopoly of hospitals. To the Minister are transferred on the appointed day all voluntary and council hospitals—the definition of voluntary hospital covering any institution for the reception and treatment of persons suffering from illness of any kind, including associated clinics, dispensaries, and out-patient departments, such institutions not being carried on for profit. So wide a definition may cover not only institutions generally regarded as voluntary and public hospitals but a number of institutions hitherto regarded as, and sometimes called, nursing-homes. There is no assurance either that such private accommodation as is taken over will continue to be used for that purpose, or that private accommodation will be retained or developed according to the public demand for such accommodation. Quite apart from this automatic transfer the Minister is given power to acquire by compulsory purchase any institution not so taken over, even though it may be conducted privately on a profit-making or dividend-paying basis.

The Committee asks that the position of private nursing-homes should be clarified by excluding such institutions, whether carried on for profit or not, from the definitions of hospital and clinic set out in Sections 9, 10, and 79 of the Act.

43. State ownership of nursing-homes is in no way essential to the efficiency of the service. It would tend to deprive the profession of facilities for independent practice. The continuance of independent practice is necessary to the maintenance of a high standard of medical service. If this is to be ensured, a Minister should neither take over automatically existing nursing-homes nor have power to acquire either those nursing-homes which are in existence or those which may be set up in the future.

44. It is the two situations—the automatic transfer and the power to acquire—regarded together that arouse the fear that a Minister, present or future, may establish a monopoly in hospitals by compulsorily acquiring, or threatening so to do, any private or voluntary hospital, home dispensary, or clinic established in the future. The Committee believes on grounds of public policy that a Minister should not be so enabled and empowered to establish a monopoly, but rather that facilities should be provided to enable private establishments to be carried on outside the service, whether on a profit or non-profit basis.

45. Under Section 6 (3) of the Act the Minister is empowered, if it appears to him that the transfer of a particular hospital is unnecessary, to "disclaim" such a hospital, subject to the right of the governing body to serve a notice on the Minister stating that they wish their hospital to be taken over. The Committee asks that an early announcement should be made of the hospitals which the Minister proposes to exempt from transfer under this Section. In the Committee's view the Minister himself should determine the principles to be applied by regional boards in considering the exemption of individual hospitals.

### Hospital Accommodation for Private Patients

46. Under Section 5 (2) the Minister may allow any practitioner serving on the staff of a hospital to treat his private patients at that hospital or at any other hospital. In the Committee's view the Minister's discretion should be replaced by an obligation to permit specialists in the service to attend their patients in private hospital accommodation.

47. It is common practice to-day to allocate a proportion of private rooms to patients of moderate income who pay fees, professional and other, in proportion to their income or to the type of room selected. It is desirable and necessary in the interests of those who pay less than the cost that there should be low ceilings to the scales of fees charged for such facilities. Maximum charges appropriate to such patients, however, would be wholly inappropriate to those who pay the full costs involved. In at least a proportion of such private beds arrangements between specialist and patient should be entered into privately and should not be subject to control by regulation.

48. Section 4, authorizing the Minister to make any available accommodation in single rooms or small wards available for patients who agree to pay for the accommodation charges covering part of the cost, may make it virtually impossible for specialists to undertake private practice. Such patients will enjoy private accommodation paying an additional sum, in the terminology of the Act only "for such accommodation." During the Standing Committee debate the Minister, in reply to a question whether medical fees could be recovered from persons who pay for special accommodation under Clause 4, stated:

"Yes. Medical fees could be recovered in certain circumstances because it might be possible that in some hospital there would be no pay block. . . ."

The Committee asks the Minister to reaffirm this statement, and to secure the necessary amendment of Section 4 to enable it to be given effect. For professional attendance there should be a sliding scale of fees varying according to the circumstances of the patient, the scale being determined by the hospital management committee with the approval of the regional board. By so much as separate rooms are set aside to provide accommodation under Section 4 for patients not paying professional fees, by so much will specialists be deprived of facilities for independent practice and by so much will patients of moderate

means be deprived of facilities for obtaining private treatment which they now enjoy. Hospital services should be planned so that all classes of the community may obtain the accommodation they desire. Patients should not be deprived of the opportunities which they now enjoy of arranging to be treated as private personal patients.

49. Implicit in the provision authorized by Section 4 is the principle of grant-in-aid, the patient paying only the additional cost in respect of the accommodation. In the Committee's view the same principle should be extended to patients who pay the full cost of private treatment in the private accommodation referred to in Section 5 of the Act.

50. Where the professional services of a radiologist or pathologist are required for a patient occupying a private ward, the radiologist or pathologist should receive a fee for his services in the same way as any other specialist.

#### Method of Reference of Patients to Specialists

51. The Committee accepts the general principle that the National Health Service should provide a full specialist service. In its view there should not be conferred on the patient the right to consult a particular specialist. It considers that: (a) Patients should be referred to specialists only at the request of a general practitioner; (b) It is desirable that a written communication from the general practitioner should accompany the patient; and (c) Facilities for diagnosis should be made directly available to general practitioners, whether in hospital or elsewhere.

#### Appointment of Specialists

52. Appointments in non-teaching hospitals at levels corresponding to those of the present honorary staffs will be made by Regional Hospital Boards on the advice of Advisory Appointments Committees. It is understood that appointments to the junior staff, up to and including the registrar level, will be made by hospital management committees with formal approval by the regional board. There should be an early announcement of the precise constitution of advisory appointments committees. The Committee stresses the need for a close liaison between teaching and non-teaching hospitals and considers that, so far as the appointment of specialists is concerned, there should be representation on the advisory appointments committee both of the hospital management committee and of the university concerned, with provision for the attendance as observers of external assessors. The Committee recognizes that, though it is desirable, it might be impracticable to have a common advisory appointments committee selecting candidates for both teaching and non-teaching hospitals.

#### General Terms of Service

53. The Committee recognizes that any decision on specialist remuneration must await the report of the Spens Committee. In regard to the mode of remuneration it recommends:

(a) That for *hospital work* remuneration should be by annual payments generally related to status, responsibility, and estimated total time spent in the service, and possibly also to length of service;

(b) That for *domiciliary work* remuneration should be on the item-of-service basis and that specialists should be free to determine whether or not they will undertake an obligation for domiciliary work under the service.

Appointments for domiciliary visits should be made by the hospital concerned on the application of a general practitioner. Each hospital should keep a list of specialists undertaking domiciliary work, including days

and hours at which they will be available. Except in emergency, patients should be permitted to consult the specialist of their choice, subject to his availability.

#### Boards of Governors of Teaching Hospitals; Hospital Management Committees—Chairman

54. The Committee considers that after the initial appointments boards of governors of teaching hospitals and hospital management committees should be permitted to appoint their own chairman.

### LOCAL HEALTH AUTHORITY SERVICES

#### Statutory Health Committees

55. The Act requires each local health authority to appoint a health committee and that a majority of the members shall be members of the authority. The Committee's view is that local health authorities should be required to co-opt to the health committee medical practitioners representative of the local profession. In a circular to the authorities the Minister, while not accepting the view that these authorities should be required to co-opt medical representatives, has emphasized the importance of the inclusion on health committees of proper representation of the profession.

The Committee has collected information on the extent to which these powers of co-option have been exercised from 42 of the 62 county councils and 57 of the 83 county borough councils. Of the 99 authorities in respect of which information is available 94 have co-opted a total of 138 members of the profession, and five authorities have decided not to co-opt medical practitioners.

#### Remuneration

56. The Committee attaches importance to the principle that the remuneration and conditions of service of all medical officers employed by local authorities (including those which are not local health authorities within the meaning of the Act) should be negotiated at the same time and through the same machinery.

#### Decentralization of Local Health Authority Services

57. In county areas the Minister has advised local authorities that the best method of organizing the county administration of the services enumerated in Part III of the Act is by the subdivision of the county into local health areas, with a subcommittee of the county health committee exercising delegated functions for each area. Such local subdivisions will be based on the general health considerations of the locality rather than on the areas already determined for the purposes of divisional administration under the Education Act, 1944.

Where such schemes of delegation result in county district medical officers of health losing the major part of their present work there should be adequate compensation for loss or partial loss of office. In the Committee's view it ought to be made possible for such medical officers to claim and receive compensation in lieu of accepting new posts offered by a county council merely with a view to finding them work without loss of salary.

### MENTAL HEALTH SERVICES

#### Division of Responsibility

58. The Committee is anxious about the division of responsibility for the mental health services between regional hospital boards and local health authorities, and wishes to stress the importance of securing a close liaison between specialist psychiatrists working in these two fields.

There should be available to local health authorities the services of a practitioner of specialist standing in psychiatry and mental deficiency. Local health authorities might be grouped to employ such an adviser and encouraged to make "joint user" appointments in consultation with regional or teaching hospital boards.

#### Regional Psychiatrists

59. The Committee attaches considerable importance to the appointment of regional psychiatrists. It emphasizes that the remuneration attaching to these posts should be of an order sufficient to attract psychiatrists of the highest ability.

#### SUPERANNUATION

60. The Committee regards as unsatisfactory the omission from the Superannuation Scheme of: (a) Provision for "added years" to compensate for the long period of training before medical qualification and the relatively late age of entry to the service. (b) Some form of immediate cover (whether by "added years" or the reckoning of non-contributing service) against permanent-incapacity or death in the early years of service. This applies particularly to practitioners who are 55 years of age or more on the appointed day.

61. So far as the profession is concerned the proposals for widows' pensions are inadequate. The basic minimum of one-third is too low, especially in view of the substantial reductions that may be made in cases where the widow is younger than her husband.

62. Consideration should be given to the desirability of extending the Scheme: (a) to include provision for the transfer of superannuation rights for medical officers who transfer from the local government service to the university service; and (b) to include superannuation facilities for secretaries and dispensers of practitioners who enter the service.

#### REPRESENTATION OF THE PROFESSION ON ADMINISTRATIVE BODIES

63. The Minister, during the Second Reading debate in the House of Commons, expressed the view:

"In fact, the whole scheme provides a greater degree of professional representation than any other scheme I have seen." (*Hansard*, col. 52, April 30, 1946.)

The Committee does not share the Minister's view. It is far from satisfied with the extent to which the Minister has appointed the profession's nominees to the Regional Hospital Boards. For example, the British Medical Association nominated 85 members of the profession for the 14 Regional Boards, an average of six per region. Only 27 of these nominees were appointed by the Minister. In five regions only one of the six practitioners nominated was appointed; in five regions two of the six were appointed, and in the remaining four regions three of the six were appointed by the Minister. The Royal College of Surgeons nominated a total of 31 practitioners, of whom seven were appointed by the Minister, including one who was also a B.M.A. nominee.

At the time of this report the membership of the Central Health Services Council has not been announced.

So far as local health authority services are concerned the extent to which county and county borough councils have exercised their powers of co-option to health committees has already been discussed under paragraph 55.

The Committee desires to remind the Minister of his statement during the Second Reading debate:

"I believe that democracy exists in the active participation in administration and policy. Therefore I believe that

it is a wise thing to give the doctors full participation in the administration of their own profession."

#### POWERS OF THE MINISTER

64. The Act involves an excessive concentration of power in the hands of the Minister. He will appoint the Central Health Services Council and its committees. He appoints the Regional Hospital Boards, which will in turn appoint the Hospital Management Committees. He will determine by Regulation a wide variety of issues, including mode and amount of remuneration. He will determine the issue of the continuance of a practitioner in the general medical service without a right of appeal to the Courts. The majority of Regulations the Minister makes will become law from the moment he makes them, subject only to their annulment by a Prayer in the House of Commons. He will deal with many important subjects by Orders which are not subject to Parliamentary control.

#### MAIN POINTS OF THE NEGOTIATING COMMITTEE'S CASE

65. In many respects the Act as it now stands is unacceptable to the medical profession. The main points which need modification, in most cases by amendment of the Act, to secure the approval of the majority of the profession include:

##### 1. Distribution

Doctors should be free to determine without pressure, direct or indirect, whether or not to enter the public service. If they decide to enter the service they should be free to choose their area of practice.

##### 2. Buying and Selling of Practices

It is in the best interests of the public and the profession that general practitioners should retain the ownership of the goodwill of their practices. This ownership provides an important incentive, encourages good and keen work, provides a basis for co-operation between practitioners and a bond between doctors and their patients. Although in this document emphasis is laid on the unworkability of the Act in this regard, the issue of ownership of goodwill is regarded by the medical profession as fundamental to its freedom.

##### 3. Remuneration

Remuneration of general practitioners should be by capitation payments in proportion to the number of persons on a doctor's list, except where special circumstances justify some other method of payment, and the Act should be so amended to provide for this, as in the Northern Ireland Bill. The Minister has accepted in principle the majority recommendations of the Spens Committee, and the profession asks for his views on the translation of those recommendations into terms of actual remuneration.

The remuneration of specialists for hospital work should be on the basis of annual payments and for domiciliary work should be on the item-of-service basis.

##### 4. Right of Appeal to Courts

There should be a right of appeal to the High Court against a decision to remove a practitioner's name from the list(s) of any or all executive councils.

##### 5. Midwifery

It is inconsistent, unnecessary, and undesirable that the Minister should seek to impose upon practitioners undertaking midwifery in England and Wales a qualification which is not imposed by the Medical Acts or upon practitioners undertaking midwifery in Scotland and Northern Ireland.

##### 6. Administrative Bodies

Executive and other councils and committees set up under the Act should elect their own chairmen.

##### 7. Public Hospitals

It is undesirable that a Minister should be empowered to establish a monopoly in hospitals. Private nursing-homes,

whether carried on for profit or not, should be excluded from the definitions of hospital and clinic set out in Sections 9, 10, and 79 of the Act.

#### 8. Hospital Accommodation for Private Patients

The Minister's discretion should be replaced by an obligation to permit specialists in the service to attend their patients in private hospital accommodation. In at least a proportion of such private accommodation arrangements between the specialist and the patient should not be subject to control by Regulation.

#### 9. Facilities for Diagnosis

Facilities for diagnosis, including radiological and pathological services, should be made directly available to general practitioners, whether in hospital or elsewhere.

#### 10. Statutory Health Committees

Local health authorities should be required to co-opt to Health Committees medical practitioners representative of the local profession.

#### 11. Public Health Service

The remuneration and conditions of service of all medical officers employed by local authorities (including those which are not local health authorities) should be negotiated at the same time and through the same machinery.

#### 12. Representation of the Profession on Administrative Bodies

There should be adequate representation of the medical profession on administrative bodies concerned with Parts II and IV of the service, such representation being arranged by the Minister in agreement with, as well as after consultation with, the appropriate medical organizations.

### POSTSCRIPT

66. The Act as it stands is full of legal perplexities and anomalies which could only be resolved, if at all, after prolonged litigation accompanied by widespread uncertainty among the profession and the public. Many of the Act's provisions are fraught with the risk of grave hardship to patients and with serious injustice to doctors and their dependants. Even with the utmost good will on the part of the medical profession, the wording of the Act is in places so obscure that to bring it into force as it stands will create chaotic conditions. The Committee offers these views as the mature conclusion of many months of detailed study of the Act carried out in company with officers of the Ministry.

When the reply from the Minister is conveyed to the Negotiating Committee it is proposed to circulate to the profession both the Committee's memorandum and the Minister's reply.

The next step will be for the profession as a whole, by plebiscite and meeting, to decide its attitude. As the Minister so plainly put it in his letter of Jan. 6, 1947, to the Presidents of the Royal Colleges: "Every doctor will have to decide for himself when the proper time comes whether or not he should take part in the new service, and the profession as a whole will be free to determine their views on the service when they know what it is to be."

In the light of the Minister's reply the profession will proceed to determine its views on the service.

November 7, 1947.

## NATIONAL HEALTH SERVICE ACT, 1946

### SECTIONS 35 AND 36

#### JOINT OPINION OF SIR CYRIL RADCLIFFE, K.C., AND MR. J. H. STAMP

In our opinion the provisions of Sections 35 and 36 of the National Health Service Act, 1946, are too ambiguous to enable any confident opinion to be formed as to their construction and effect in relation to medical partnerships whose members on the appointed day under the Act are, or include, practitioners on the list for general service. There can, we think, be no reasonable certainty as to the answer that would be given to the questions that arise under the sections by the highest tribunal that may be required to adjudicate upon them, and only such an adjudication can finally resolve the meaning of any ambiguous document. Further, on every possible construction of the sections serious difficulties arise which cannot be evaded by any Regulations authorized by the Act, and this is particularly the case if the view at present favoured by the advisers of the Ministry prevails that options and obligations to purchase contained in subsisting partnership agreements are kept alive by the final provisions (which have been conveniently but inaccurately referred to as the "proviso") of Subsection (4) of Section 35 of the Act.

If Sections 35 and 36 are allowed to become operative without amendment the profession and the Ministry alike will labour under embarrassing uncertainty on matters of great importance until the debatable matters have been finally adjudicated upon, and in the meantime steps may have been taken on the footing of a construction which is ultimately found erroneous with unfortunate consequences to all concerned. In our opinion it would involve a real hardship to the practitioners concerned if they were required to submit to such uncertainty when it has been clearly foreseen and can be removed by an amending Act.

It appears to be suggested that difficulties may be removed by suitable Regulations under the Act, but such Regulations cannot amend the Act, or affect its construction. In any conflict between the Act and Regulations made under it the Act must prevail. The Ministry cannot by any expression of official opinion or by any Regulation prevent the construction of the

Act from being tested by the Courts and, if past experience can be trusted, it is highly probable that sooner or later some practitioner or combination of practitioners will be, or think itself to be, sufficiently interested to challenge the official view, and carry their challenge, if necessary, to the House of Lords. This possibility may keep the uncertainty alive for many years.

The official view of Section 35 may be regarded from three different aspects: (1) What, under Section 35, are the factors for and against it, and the alternative to it? (2) How does it square with the provisions of Section 36 as to compensation? And (3) What as a matter of practice and policy is there to recommend the official view as compared with alternative constructions that might be adopted by the Court or by an amending Statute?

#### 1. Factors For and Against the Official View

The official view rests upon the implications found by its supporters in the "proviso" to Subsection (4) of Section 35. After providing in paragraphs (a), (b), and (c) that in the events therein mentioned there shall be deemed to have been a sale of goodwill the section by the "proviso" enacts that "the said sale shall be deemed . . . to have been effected (i) in a case to which paragraph (a) or paragraph (b) applies, at the time when the consideration was given or, if the consideration was not all given at the same time, at the time when the first part thereof was given; or (ii) in a case to which paragraph (c) applies, at the time when the agreement was made." Upon this provision it is argued that all the terms of the partnership agreement form a single contract and that every one of its terms is part of the consideration for all its other terms so that part of the consideration for every sale provided for by the agreement goes back to the inception of the partnership. This argument is supported by the observation that Subsection (4) clearly contemplates that service in the partnership

may be a valuable consideration for a transaction deemed for the purposes of the section to constitute a sale.

This argument is somewhat *recondite* but for all that it is by no means to be rejected as impossible. In our opinion, however, (a) if it was in fact the intention of the legislature to keep alive all purchase provisions in subsisting partnership agreements it is strange that it should have been content to allow an intention of such importance to be elicited from the Act only by so subtle an argument, when it could have been quite simply expressed, and (b) in our opinion the argument overlooks the true scope and effect of Subsection (4) and its "proviso."

The placing of Subsection (4) in the section between Subsection (3) and Subsection (5), each of which has as its purpose to prescribe "deemed" sales for the purpose of the section, is to us significant. It seems clear that the primary purpose of Subsection (4) is not to protect any subsisting agreements from interference by Section 35 but to bring within the prohibition of the section various transactions so framed as not to have the technical character of sales but having in fact a similar effect which the legislature intends to prevent; and this is in truth the only effective operation of its substantive enactment. Plain undisguised sales under the Partnership Agreement would come within the section without any aid from Subsection (4), transactions which require to be "deemed" to be sales alone require its aid. The wording of the subsection was inevitably such as to cover sales in the true sense, but this does not in our opinion affect the foregoing statement. The use of the expression "shall be deemed to have been a sale" in the operative sentence of the subsection is, we think, very significant of its object to bring in transactions which are not in truth sales.

The official view depends ultimately, however, upon the "proviso," and in particular upon the assumption that the considerations which under the proviso determine the dates of the transactions to which it relates include the day-to-day services that partners render to one another, through the partnership, in performing their ordinary duties as partners. Nothing less than this will suffice, and in our opinion the assumption is not justified.

The object of the proviso is to fix the statutory date of a transaction deemed to be a sale under the earlier part of the subsection; it relates to the "said" sale, where the word "said" is significant, and it follows in our opinion that the "consideration" referred to in the proviso is a consideration referred to in the earlier part—i.e., the consideration by virtue of which the earlier part applies to the transaction. Such considerations do not in our opinion include, in the case of an ordinary partnership, the day-to-day service of the partners. In this context the three paragraphs of Subsection (4) must be referred to.

Under paragraph (a) services in the partnership are expressly excluded from ranking as considerations for a sale, and under paragraph (c) they rank as considerations for a sale only when otherwise they are insufficiently remunerated. There remains paragraph (b), upon which supporters of the official view must rely. Its leading terms are "any valuable consideration is given to a partner, on or in contemplation of his retirement or of his acceptance of a reduced share of the partnership profits, or to the personal representative of a partner on his death," and in our opinion there is no justification for attaching to the words "in contemplation of" any other than their ordinary natural meaning, which confines the reference to considerations directly associated with a contemplated retirement, and does not include any day-to-day duties performed in the ordinary working of the partnership, which would go on just the same whether a retirement were or were not in contemplation.

If the foregoing analysis of Subsection (4) is correct the official view is necessarily displaced.

An additional difficulty in adapting paragraph (b) to the official view is that in the case of a sale by executors the words "or in contemplation of" do not grammatically apply and the paragraph contains no grammatical justification for dating back any part of the consideration.

This does not, however, involve as a consequence that all purchase provisions in current partnership agreements are invalidated, for some such provisions will fall within the terms of paragraph (c) and will consequently be saved by the "proviso." This paragraph covers cases in which "services

are performed by any partner for a consideration substantially less than those services might reasonably have been expected to be worth." In such cases the partner in question has been actually earning the right to take over another partner's share of the goodwill by contributing to the partnership the otherwise unremunerated fraction of his professional services, and if he were prevented from calling for his purchase he would be deprived of the benefit of this contribution, which does not on any natural interpretation of Section 36 confer any right to statutory compensation.

The result of the foregoing reasoning is that in our opinion purchase provisions contained in subsisting partnership agreements are saved by the proviso only in cases coming within paragraph (c) of Subsection (4) but not in other cases.

It seems obvious that the existence or even the probable existence of this difference between the effect of partnership agreements which, on the face of them, may be in identical terms must be a cause of serious embarrassment to the partners concerned. It must often, especially after a lapse of years be a difficult question of fact whether paragraph (c) does or does not apply to any particular partner; but on it will depend not only rights as between the partners but also rights of compensation.

## 2. How Does the Official View Square with Section 36?

In our opinion the compensation provisions of Section 36 cannot on any reasonable construction be made to square with the official view of Section 35 or with the construction which we feel constrained to put upon paragraph (c) of Subsection (4) of Section 35 taken in conjunction with the "proviso" to that subsection.

The first question that arises under Section 36 is whether the practice in respect of which a practitioner is to secure compensation is his practice at the appointed day or his practice at the date at which the question of selling it would in fact arise.

In our opinion the answer to this must be that it is at the appointed date. We do not think that the wording of Subsection (1) of Section 36 is well conceived to achieve this construction, since it is the right to sell his share of a practice at any time in the future that Section 35 deprives a listed practitioner of, and it is compensation for the loss inflicted on him by Section 35 that Section 36 is expressed to provide. But it would in our opinion be wholly impracticable to put off the ascertainment of the compensation payable in respect of each practice until the time came in the ordinary course for its sale as on that footing not only could no compensation be fully ascertained until a relatively remote date in the future but the payment of interest would be impossible with any degree of accuracy, even if the persons ultimately becoming entitled to it were ascertained. In the meantime payments on account could at the most be made.

In the case of single practitioners there is no further question or difficulty, but it is far otherwise in the case of partnerships. Taking, for example, the simple case of two practitioners, both on a general list, operating under a partnership agreement containing a provision that on the death or retirement of either the other should purchase his share. It is obvious that if Section 35 does indeed secure that the purchase provisions are to remain in force the partner who first retires or dies will suffer no loss and ought to receive no compensation under Section 36. On the other hand the continuing partner will suffer a double loss through being forced to purchase the now unsaleable share of his outgoing partner as well as having his own sterilized in his hands. This is a typical state of fact resulting from the operation of the official view, but the application to it of the provisions of Section 36 presents the gravest difficulties. Reading Sections 35 and 36, with the adjustment required in the case of a partnership by Section 35 (12), we find that under Section 35 a partner is forbidden to sell his share of the goodwill of the partnership practice and by Section 36 he is given the right to compensation for the loss suffered by him by reason that he is or will be unable to sell all or any part of his share of the goodwill of the partnership practice. These provisions require violent treatment to make them fit the foregoing state of facts. Only one of the partner

will have suffered any loss, and what he will be unable to sell is not his share of the goodwill but the whole goodwill of the partnership made up of his own share and the share purchased from the outgoing partner or his estate. Further, if interest is paid to both partners under Section 36 (3) (d) it must prove to have been wrongly paid.

It would be easy to enact that in the case of partnerships containing purchase provisions the whole goodwill should be valued as at the appointed day, but the appropriate compensation should be retained and only paid over when the course of events has shown which partner has suffered the loss and if more than one in what proportions, and that in the meantime the interest should be added to the corpus. We cannot, however, extract this meaning from the context. It involves payment of compensation to a partner in respect not of his own share of goodwill but in respect of the shares of himself and of his partners, and it also involves the non-payment of interest between the appointed date and the payment of compensation and indefinitely postpones the ascertainment of the persons entitled to compensation or the amount of their compensation.

Nor in the case of such a partnership do we think it possible to satisfy the Act by calculating the compensation by reference to the value of each partner's present and contingent interest in the partnership goodwill as a whole, treating as each partner's share of goodwill not his half or one-third or as the case may be but the proportion of the whole which may be considered most fairly to represent his portion having regard to his immediate share and the probabilities of its actually being subsequently purchased by another partner or of its being increased by subsequent purchase or purchases under the partnership agreement. First, this would relate the compensation to something quite different from the share of goodwill of each partner and, secondly, the effect of it would be that one of the two partners would receive compensation without ultimately suffering any loss and the other would by that same amount fail to receive compensation for his whole loss. To allot compensation to the partnership as such in respect of the whole goodwill of the partnership practice and leave the partners to partition it between themselves obviously abandons Section 36 (1) altogether and substitutes something quite different. Each partner is, we think, clearly entitled to separate compensation, and for this purpose the partners are in the same position as if they were practising separately.

It seems impossible to reconcile the payment of interest under Section 36 (3) (d) of the Act with any construction of Section 35 that would postpone to a future date the effective ascertainment of the partners entitled to compensation. The interest must in our opinion be paid to the persons effectively entitled to the compensation, and any interest not so paid will have gone to the wrong persons.

The difficulties so far adverted to can be removed by enacting without ambiguity that existing partnership purchase provisions (including the special cases intended to be dealt with by Section 35 (4) (c)) shall be avoided. This step would enable the title to compensation to be decided promptly and the payment of interest to be regularized. There seems insufficient reason for keeping existing partnerships within paragraph 35 (4) (c) having regard to the resulting difficulties.

The case of partnerships which include one or more partners who are on the general list and one or more partners who are not on the list does, however, present very special difficulties which cannot be simply dealt with. The case can be examined by taking the case of two partners—one ("A") on the general list and the other ("B") off it—operating under an agreement containing mutual purchase obligations on retirement. The prohibition on sales in Section 35 has no application to "B's" share, so that if he is the first to die or retire, whatever may be the construction of that section, "A" will be bound to purchase his share. Plainly he will be in a great difficulty under Section 35 (1) if he wishes to resell the share; will it be part of the "goodwill of the practice" of "A" so as to be caught by Section 35 (1)? If so he will be forbidden to resell. Presumably this will be the case, for presumably when a partner buys in his partner's share of the goodwill the whole goodwill becomes his and the purchased goodwill becomes in consequence part of the goodwill of his practice.

If he is forbidden to resell, is he entitled to compensation? The answer to this question is not easy, but there is serious difficulty whichever way it is answered. If in the negative, injustice will be done to "A": if in the affirmative, the operation will bring the value of an entirely fresh practice within the scope of the compensation provisions of the Act—i.e., the share of "B," who has not come upon any general list, so that the share in his hands carried no restriction on sale and no right of compensation and is only brought within the Act by its transfer to "A." If under the Act as it stands the share carries compensation the allocation of the compensation fund will be kept open until the last partnership of the type has come to an end. If it does not, a new statute would be necessary in order to enable the extra sum required to be provided. A Regulation under the Act to that effect would be *ultra vires*. In our opinion it would be a case for a new statute.

If on the other hand "A" is the first to retire, then according to the official view "B" will be bound to buy his share and "A" will have no claim to compensation. This contingency produces no new difficulty of construction but it is highly unsatisfactory from "B's" point of view. It is true that he might have a right to sell the goodwill (if it really exists) that he has bought from "A" or "A's" executors, but he can neither make use of it himself nor in fact sell it inasmuch as a list practice from its very nature is likely to be a practically unsaleable asset. His own practice not being a list practice will be a more marketable asset if there are any buyers.

The case of "mixed" partnerships does not appear to have been considered by the draftsman of the sections, but it plainly calls for express statutory treatment. The best solution may perhaps be to cancel the obligations on the footing that this will not harm the "listed" partner and that in the case of the other partner release from a possible liability to purchase a "list" practice will compensate him for the loss of a secured purchase of his own practice leaving him free to sell on the market.

### 3. Policy

It appears to us to be very decidedly preferable that purchase provisions in partnership agreements between practitioners on the general list should be cancelled at once (in accordance with the effect of the sections as any ordinary intelligent reader would almost certainly understand them) and allow each partner to receive compensation in respect of the share which is his share at the appointed date. Each will then have received compensation whether, if the purchase provisions had stood, he would have in fact sold his share under those provisions or not, the compensation taking the place of the purchase money that he would have taken from his partner if a sale under the partnership agreement had taken place. In that case any partner who, if such a sale had taken place, would have been the purchaser should at the appropriate time take the share without payment. This in our opinion would be right, because if he had purchased the share the only fair course would have been that he should receive the compensation in respect of it, so that, if the compensation was adequate and the price fair, the two would have balanced, and the net result would have been the same as if he had taken the share without payment. If the right to purchase a share were cancelled without leaving any right to acquire it, a serious injustice would be done to junior partners who had entered a partnership with a "small" share in reliance on a right to purchase a further share or further shares in due course.

If purchase provisions are kept alive so that a purchase price and statutory compensation are paid in effect in respect of the same transaction there will be likely to be great discontent whenever the two amounts are substantially different.

To keep alive rights or obligations of purchase over "list" practices appears to us to be really inconsistent with the intention of the Act that there should be no goodwill in such practices. If a list practice is not a saleable asset this must apply as much between partners under existing partnerships as between future partners.

# THE NATIONAL HEALTH SERVICE AND THE MEDICAL PROFESSION

## GENERAL COMMENTS OF THE MINISTER ADDRESSED TO THE INDIVIDUAL DOCTOR

The Minister's memorandum on the Negotiating Committee's statement about the National Health Service follows. The Secretary of State for Scotland associates himself with the memorandum, which may therefore be read as applicable (with the necessary changes) to the service in Scotland so far as conditions in that country are the same as in England and Wales.

The memorandum deals only with the points raised by the Committee. But, for the individual doctor, there are other—simpler—matters on which he wants to know exactly where he stands. If he participates in the new health service, how does it affect him personally?

Hardly any major step to better social services (in which doctors, above all, are interested) has provoked more mis-statements or misunderstandings than the National Health Service Act. The Minister would like to take this opportunity, in preface to his main memorandum, of clearing some of the more fundamental points which must be exercising many doctors' minds. He can only deal with some of these in this paper—but on any others he will be glad to try to help doctors to understand what the scheme means to them if they will get in touch with his Department.

Here are some of the points, mainly affecting the general practitioner:—

### What Does Taking Part Mean?

(1) Any doctor, like any other member of the public, can participate in the new scheme or not—or partly do so and partly not—just as he thinks fit. There is no compulsion whatever.

(2) Any doctor participating can also retain private practice. This and other professional services for fees or other remuneration, other public or private medical work, may go on. The only limitation is that no fees may be charged to patients whom he has accepted on his list within the scheme.

(3) "Service" is perhaps a misnomer—if it is thought of as an organized corps, like the medical branches of the Fighting Services. Nor is there any hierarchy of "supervision" or interference with a doctor's professional judgment and clinical practice. He undertakes to look after patients and is left to do so in his own way and to the best of his clinical ability. He is not "under orders."

(4) He is not "employed." He enters into an arrangement with a Local Executive Council (half professional, doctors, dentists, and chemists) which takes the place of the old insurance committee, and, in essence, his contract is to look after the patient whose care he undertakes—and to be paid for it from public funds, in these cases, instead of by private fee. He is certainly not a civil servant.

### How Will the Doctor be Paid?

(5) What is this payment from public funds? It is set out in detail in paragraphs 26 and 27 of the main memorandum attached. But examples of it can be usefully given here.

If a doctor takes on 4,000 potential patients under the new scheme, his gross income from this source would be £3,300. If his number is 3,000 potential patients, the gross income is nearly £2,600. In addition he may have private fees from other patients, other public or private paid appointments, additional fees for undertaking maternity work, mileage allowances, allowances for training assistants, and other extras.

(6) Also there will be a fund of over £400,000 a year available for discretionary payments as "inducements" to assist practice in difficult and unpopular areas.

(7) The aim will be to set 4,000 as the maximum number of patients for a doctor under the scheme, but there is no rigidity in this.

(8) All of this assumes that no less than 95% of the population use the new service. If the figure is less, the payment per patient is proportionately higher. But in two years' time that position will be reviewed. It is the essence of a successful national service that both doctors and the Government co-operate in getting the nation as a whole to benefit by it.

### Compensation and Superannuation

(9) Doctors who participate in the scheme on the appointed day will establish their claim to their share of the £66,000,000 which the Government has set aside as compensation for their being unable in future to sell public practices. The sum of £66,000,000 represents an amount agreed with the profession's representatives. The Minister is prepared to take the profession's own advice as to how this is to be most equitably distributed. Normally it will be payable when capital values would otherwise be realized—on retirement or death—with interest in the mean time. But if there is hardship, like some undue debt burden on the practice, it can be paid at once. If a doctor wants, later on, to stop practice for any reason he can draw his compensation at once and do so.

(10) In addition, a superannuation scheme is to be started; the doctor contributing 6% of the payment he receives in the new service (less a percentage for "practice expenses") and the Government 8%; the benefits to include a pension and a lump sum on retirement (including retirement on incapacity), a death benefit, and a widow's pension.

(11) The profession's representatives think that partnership agreements will be prejudiced by the new arrangements. The Minister is advised otherwise, as will be seen (see paragraphs 14 to 22 of the main memorandum). But, if the Minister finds, on any judicial decision, that he is wrong, he undertakes to introduce legislation to restore his original intentions, as indicated in the main memorandum.

### No Direction of Doctors

(12) All existing doctors can participate in the new scheme where they are practising now. After the scheme is operating a doctor wishing to participate—and draw public remuneration—will need to get consent from a public medical body to be set up. Private practice is, of course, unaffected. Consent in respect of public practice will only be refused in those few areas where there is clearly no need for additional "public" practice. (This is dealt with more fully in paragraphs 6 to 13 of the main memorandum attached.) No doctor can be directed anywhere.

(13) Under the old National Health Insurance Scheme a doctor can be debarred by the Minister from continuing to participate. In future he can only be so debarred by a special and statutory tribunal—a lawyer (appointed by the Lord Chancellor), someone representing the Executive Councils, and a doctor. If they do debar him, he can still be retained by a successful appeal to the Minister. If they

decide he should remain, the Minister has no power to intervene. The advantage lies only with the doctor.

(14) Although a doctor may not get consent to opening a surgery for practice with the scheme in a particular area (on the grounds that it is not needed) he can accept patients from any area he wishes as long as he is prepared to visit them as necessary.

(15) As and when health centres are set up, no doctor will be compelled to practise in them. Their object will be to provide premises and equipment, usually costly for the doctor to provide for himself, and to enable him the better to treat his patients. In health centres the personal relationship (of "my doctor") will be retained. There is no question of setting up "institutions" where the patient has to see the doctor "on duty." They will be a substitute for the doctor's home surgery, publicly serviced and equipped. Group practice, like present partnerships, will be encouraged in them.

#### Assistants

(16) Assistants, paid by the doctor, will permit—as before—of enlarged lists of potential patients. In addition there will be a system of grants to doctors for the training of young assistants—still to be worked out in detail in consultation with the profession.

#### Doctors in the Running of the Service

(17) Doctors are, for the first time, brought on a substantial scale into every main field of administration of the new scheme—Regional Hospital Boards, Boards of Governors of Teaching Hospitals, and Executive Councils. It is a new experiment in bringing the profession itself into the direct administration. In addition there is to be a

Central Health Services Council, with a majority of doctors (to advise the Minister on the whole scheme) and a special Statutory Advisory Committee of the Medical Profession. Both can advise without being asked, and the Minister has to publish the Council's report (save only where the public interest prohibits).

#### General

It is the very essence of a doctor's relationship to his patients that it should be personal and confidential. The scheme in no way interferes with that. The object of the new Act is a simple one. It is to help, by public funds, to ensure that anyone—the highest and the lowest—should be confident of getting all the best that a great profession can give. If the profession rally to it the greatest health service in the world can come into being. There is no reason whatever why the personal relationship of doctor and patient—and the professional independence of the doctor—should be affected by a switch-over from private fees to public funds.

A scheme of this magnitude is bound to need correcting, amending, as it is found wanting. But, in its conception, it is something of incalculable social value to the great mass of the population, and the medical profession will be the first to want—as they have wanted—something of this kind. For his part, the Minister is concerned mainly to get this great national scheme launched, and to plan on wider, better lines, with the profession directly co-operating in the management of the new service. He asks the profession to help him in launching it next year and in constantly improving it as it goes along. It is a big thing, and he is confident that the profession will join with him, as constructive and often properly critical partners, in getting it under way.

## THE MEMORANDUM OF THE MINISTER ON THE STATEMENT OF THE NEGOTIATING COMMITTEE'S VIEWS

1. The Minister has studied the statement of the Negotiating Committee's views. He has also discussed its main points in meetings with their representatives on Dec. 2 and 3, 1947, and the subject matter of the statement has been discussed in greater detail earlier with his officers.

2. The Minister now sets out his own views, following on the discussions, and in doing so follows the same subject headings as the statement—for ease of reference.

#### PRELIMINARY

3. The Minister agrees with the account given of the events leading up to his discussions with the Negotiating Committee. He has never excluded—and does not now exclude—the possibility of amending legislation being found desirable. Indeed, in his experience, it would be most unusual if points for amendment were not discovered sooner or later in any measure of the scope of the National Health Service Act. He expects this to be no exception. But the discussions have not convinced him of any sufficient reason to go to Parliament and ask it to alter its intentions as to the new service before that service has been tested in actual operation and found to need amendment. If, when the time comes, it is so found, the Minister will not only be willing to seek—but will himself be the first to wish to seek—its modification and improvement by Parliament.

4. Meanwhile, within the framework of the Act and in its administration, there is clearly room for those adjustments which result from discussion and which are the purpose of discussion. These are dealt with, point by point, in the rest of this paper. The Minister will certainly be prepared to give effect to them, and he assumes that the

profession, for their part, will whole-heartedly help him in making the new health service the success which both they and he want it to be.

#### THE PROFESSION'S AIM

5. The Minister has again examined the seven general principles set out in the Committee's statement, and he does not believe that anything in the proposed National Health Service is really in conflict with them.

#### GENERAL PRACTICE

##### Distribution

6. The decision of Parliament to assure all people the opportunity to benefit from a full medical service—which the Committee approve in their statement—involves the placing of responsibility somewhere for watching the reasonable distribution and availability of that service. A public duty cannot be undertaken without any reasonable means of fulfilling it. Public money cannot be attracted to practice in areas where the public interest does not warrant it. Even so, the Act deliberately avoids any power of "direction" of doctors (such as is mentioned by the Negotiating Committee's fourth stated principle). All existing doctors can take part in the new arrangements where their practice lies, without disturbance. After that, and for the future, there is reserved to the new health service the right only to say in what areas it has no need for additional participants or replacements—for its own purposes. This has nothing to do with, and does not affect, private practice.

7. Nor is it the Minister who will normally decide this, but a mainly medical body (the Medical Practices Committee) specially set up for the purpose and not subject to

his direction. A doctor, having been refused participation in the new service in a given area, can appeal to the Minister; but it is a one-way appeal (for the doctor, and not against him)—i.e., the Minister can reverse the committee's decision and turn it in the doctor's favour, but cannot reverse what the committee have allowed and turn the decision against the doctor. The "worst" that the Minister can do, from the doctor's point of view, is to uphold a decision already reached by the professional Medical Practices Committee.

8. In the Minister's view, and the view endorsed by Parliament, this is the minimum public intervention in the distribution of a public service which could possibly be justified to the country and the taxpayer when the new situation, of a public undertaking to see that all people can get what they need, has come into being. To go beyond this would be, not a question of the right to practise privately anywhere (which doctors will still be perfectly free to do), but a question of giving them the right to demand publicly remunerated work where they like—a position which no other profession or occupation enjoys.

9. Especially when there may not be enough doctors for the needs of all the population, it cannot, in the Minister's view, be assumed that payment in respect of all—or practically all—the people will result in an equal distribution of doctors in relation to population.

10. Nor will the procedure for obtaining consent to practise in the public service in new areas be cumbersome and elaborate, as the Negotiating Committee present it. The Medical Practices Committee will, as a matter of common sense, make it its job to keep in regular touch with Local Executive Councils (the successors to the Insurance Committees) and will know the areas where there is no need for new public practice or replacement—and these will be few, for many years to come, until the number of doctors available has increased. Apart from such areas consent can usually be given automatically—unless the question of two or more claimants for one practice arises. In the latter cases involving selection and consultation with the Executive Council, the Executive Council can find out the Local Medical Committee's view and make its recommendations at the same time as it sends in the names for selection. There need be no delay, and, even in selection cases, the period of settlement should usually be nearer one month than four.

11. Such interval as there is will be dealt with by regulations. If a doctor dies and his representative wants to appoint a "locum" to look after matters temporarily, he can be authorized. Alternatively, the Executive Council itself, consulting the Local Medical Committee, can appoint a locum and make such arrangements as are necessary (including arrangement for accommodation).

12. On the point whether consent might be withheld from practice in a particular part of an area, this power to deal with parts as well as whole areas is simply designed to meet the case where the need for refusal only arises in one part of what may be a large area—such as London. It will not have the effect of stopping a patient from crossing some imaginary boundary line to consult a doctor (as the Negotiating Committee seem to think) because the Medical Practices Committee will be asked to make any such refusal only a refusal of consent to the carrying on of surgeries or centres in a specified part of the area. Although the doctor may not get consent to the surgery in that area he can accept patients from anywhere as long as he is prepared to visit them as may be needed.

13. On the whole of this question of consent to new participation in the service in new areas, it must be empha-

sized that the areas where this is likely to be found unjustifiable and redundant are few. Also, the picture is not one of a Medical Practices Committee going through an involved procedure in every individual case, as though it had each time to ascertain the situation of an entire strange area. It will be a body which exists to know the facts of the country generally, to keep up to date on them by contact with Executive Councils, and to know—in short—in which few areas it has to be specially watchful. I will, therefore, be able to act quickly and, normally, from its own knowledge.

#### Ownership of Goodwill: Existing Partnership Agreement

14. The interpretation of the Act set out in paragraph 16 of the Committee's memorandum correctly sets out what the Minister believes to be the effect of the Act (on all the legal advice which he has obtained) and also what he understands Parliament to have intended in the Act. If there are varying opinions as to the validity of this interpretation the Minister has no power to decide upon their merits; that is for the Courts. If, in the event, this interpretation is proved to be wrong, the Minister will unhesitatingly seek from Parliament such correction of the Act as will be designed to restore it. He gives that assurance without question. All of this is normal and familiar constitutional procedure. The Minister, with Parliament's endorsement does what he is advised to be right in achieving his intentions. If and when that is proved to be wrong he asks Parliament to adjust it.

15. The interpretation referred to means that the Act does not make it illegal to carry out, as between partners existing partnership agreements. Existing powers or obligations between partners to buy or sell shares of the partnership practice will remain in force and can be fulfilled. Careful provision is necessary to secure that the right proportion of compensation goes eventually to the practitioner who actually suffers the loss and that a practitioner whose share is bought by his partner does not get both the purchase money and the compensation. The methods by which it is proposed to deal with the problem are set out in paragraphs 17 to 22 below, and the Minister considers that provision by regulations on these lines will dispose of all the major difficulties, which it is his firm intention to do.

16. But suppose that his advice is wrong. It is always within the power of any partners, if they still feel that in exceptional cases some anomaly is left which is not and cannot be covered by any general provision, to vary by agreement the terms of the partnership and so to remove the anomaly.

17. Where all partners participate in the new service, the Minister proposes to provide by regulation that—

(1) compensation will be assessed in respect of the value of the partnership practice as a whole at the appointed day

(2) partners may, if they like, agree how the compensation for the practice shall be apportioned between them—an interest will then follow the agreed apportionment;

(3) failing agreement between the partners, compensation will be assessed and interest will be paid on the basis of the shares which they hold at the appointed day. Whenever the Minister is later notified that a sale of shares has taken place in accordance with the partnership agreement, the assessment of compensation will then be corresponding adjusted and interest will follow the change;

(4) in cases of hardship early payments on account of compensation will be made, subject to arrangements for securing that if the recipient's share of the partnership is afterwards bought by his partners (and he therefore suffers no loss entitling him to compensation) the compensation will be repaid.

18. The Negotiating Committee consider that such arrangements would still leave two anomalies—

(1) the price which a partner had to pay for the purchase of a further share under his agreement (which he could not re-sell) might be more than the compensation;

(2) a partner will not necessarily receive interest on the full amount of the compensation which ultimately becomes due to him.

19. The former situation will arise if the value of the practice increases as a result of the new health service (involving also an increase in the income from the practice). It might also arise in individual cases without any change in the income of the practice. The basis on which the purchase price is to be fixed varies from one agreement to another, and it is just as possible for the price so fixed to prove smaller, instead of greater than the amount of the assessed compensation. Partners who anticipate difficulty from this can, if they think it necessary, agree among themselves that the price to be paid for shares bought under the partnership agreement should be the same as, or not exceed, the compensation assessed in respect of those shares.

20. The suggestion that the payment of interest in the manner proposed by the Minister is inequitable seems to be ill-founded. Compensation is provided under the Act to meet the loss which a practitioner may suffer because he cannot sell his practice except under a partnership agreement in existence on the appointed day. Interest on compensation is paid because, until the compensation is finally paid, it has to be regarded as invested capital. It is true that this capital may change hands under the partnership agreement but until it does so it seems most equitable to pay the interest to the owner of the asset for the time being.

21. Where one or more partners do not participate in the new service the position will be as follows—

(a) compensation will be fixed in respect of the proportionate part of the partnership practice belonging to the partners who do participate;

(b) compensation and interest as between partners inside the service will be paid as in paragraph 17 (2), (3), and (4) above;

(c) a partner within the service, required to buy the share of a partner not in the service, will receive compensation for the share so bought on the basis of the value at the appointed day. The value of this share will be ascertained when ascertaining the value of the shares brought into the service;

(d) it will not be possible to compensate a partner outside the service who is required to buy the share of a partner within it. The Act is only concerned with those within the service and only the partner inside the service will be assured of compensation for any loss. Partners can, however, themselves arrange to modify their agreements so as to remove any difficulty which might arise from this obligation;

(e) when a partner not participating in the service buys the share of a partner in it, compensation in respect of that share will no longer be payable to the partner in the service—as he will have suffered no loss.

22. The effect of paragraph 21 (c) will be payment of compensation for which there is no provision in the aggregate amount of compensation. On the other hand, the effect of paragraph 21 (e) will be non-payment of compensation for which there is provision in that aggregate. For the time being it is proposed to proceed on the assumption that the excess on paragraph 21 (c) will be balanced by the saving on paragraph 21 (e), but the precise effect cannot be known for many years, and probably the balance can hardly be exact and will need later adjustment. The Committee also contend that the total amount provided for compensation will be insufficient if every practitioner in general practice takes part in the service before the appointed day. If this happens the Minister will ask Parlia-

ment to provide an appropriate increase in the global sum. All these points are matters for such later amending legislation as experience proves necessary.

### Partnerships after the Appointed Day

23. The main object of new partnerships, entered into after the appointed day, will be greater convenience and better facilities for carrying on practice. The remuneration of each partner must be assessed on the general basis of his value to the partnership, and in making this assessment account can be taken not only of his earnings but also of his knowledge, experience, and standing. There seems to be no reason whatever why this basis of partnerships should discourage them in future or why the buying and selling of shares should be regarded as the essence of a partnership in medical practice. If there is any doubt whether a proposed division of earnings is in accordance with the Act the Medical Practices Committee can be asked for their opinion; if they think the proposal is in order they will then issue a certificate which will be a complete defence if the transaction should ever be questioned.

### Assistants

24. An offence will only be committed if an assistant is paid so obviously less than he is worth as to amount to a sale of goodwill, and this is obviously not what the profession would wish to do. In case of doubt there is again the complete safeguard of a certificate from the Medical Practices Committee. This being so, the Minister cannot think that the difficulties anticipated by the Negotiating Committee are likely to arise. He entirely agrees as to the desirability of an initial period of assistantship, and he has suggested to the Committee a scheme of grants to experienced practitioners willing to train assistants, which he hopes will benefit both principals and assistants alike.

### The Doctor's House

25. Some of the difficulties anticipated by the Committee will be met by enabling the Executive Council to buy the house for the incoming doctor. For the rest the Minister is advised that there is no risk of committing an offence if the house is put up to auction *bona fide*, whoever may buy it; and in any case a certificate from the Medical Practices Committee will be a complete protection. The Medical Practices Committee was devised as a professional body so as to ensure that it would understand and pay full regard to the proper interests of the profession in the matters before it, and it will have a wide measure of discretion.

### Remuneration

26. The Minister proposes the following arrangements in order to translate the general recommendations of the Spens Committee (which he has already accepted) into actual terms of remuneration for general practitioners (the Spens Committee on Specialists not having yet reported):—

(1) A central fund as contemplated in paragraph 41 of the Negotiating Committee's statement (coupled with the assumption by the profession of collective responsibility for all who wish to use the new service) will be established—equal to a capitation fee of 18s. multiplied by 95% of the civilian population.

(2) This 95% of the population, by which this 18s. is multiplied before being put into the fund, will be reconsidered at the end of two years, having regard to the aggregate number of people who are in fact found to be using the new service at that date.

(3) There will be a first charge on that fund for—

(a) allowances for mileage (which may be in a separate sub-fund), fees for temporary residents, emergencies and

anaesthetics, on the general lines followed in the National Health Insurance Scheme;

(b) a sum sufficient to distribute to every doctor taking part in the service, on an Executive Council's list, a fixed annual payment of £300 a year—subject to conditions to ensure that some reasonable minimum number of patients is accepted by such doctors within a reasonable period.

(4) The remainder of the fund will be distributed to each Executive Council area on the basis of a capitation payment multiplied by the number of people on the doctors' lists in that area, plus one-third of the number not on the lists. This would then be distributed among the doctors taking part in the service in the area in the form of a capitation fee for each person on each doctor's list.

(5) In addition, a sum equal to 1% of the central fund (about £400,000) a year will be attached to the central fund for use in providing discretionary extra "inducement" payments—in addition to the fixed payment under (3) (b) above—to assist doctors to practise in peculiarly difficult (e.g., sparsely populated or unpopular) areas. Any unexpended balance of this sum will periodically accrue to the main central fund. The award of these inducement payments will in each case be determined by the Minister after taking the advice of the Medical Practices Committee—general principles as to the basis of that advice being first settled with that Committee and in consultation with the profession.

(6) Payments met otherwise than from the funds described above will be maternity fees, special grants for training assistants, and payments for drugs.

(7) The apportionment of the central and other funds or sub-funds, between England and Wales on the one hand and Scotland on the other, has still to be settled.

(8) Special machinery for negotiating future revisions of the terms of remuneration is at present under discussion with the profession.

(9) In addition, of course, there will be the superannuation scheme, the benefits of which are already familiar.

27. On these remuneration proposals, the following points are of interest:

The estimated civilian population of Great Britain at June 30, 1948, is	47,750,000
Therefore, 95% of this number is	45,362,500
A payment at the rate of 18s. per head of this number would produce a Central Fund of	£40,826,250
Assuming 17,900 principals take part in the service, the deductions to be made from this amount would be—	
(a) 17,900 fixed annual payments @ £300	£5,370,000
(b) Mileage payments, say	£1,000,000
	£6,370,000
Leaving a net amount to be distributed of	£34,456,250

If the full 95% of the population were actually on doctors' lists the payment per head (additional to the £300 fixed sum) would still be ... 15s. 2d. (approx.)

The gross income (exclusive of receipts from private practice, obstetric service, mileage, etc.) would be—

1,000 public patients	£300 + £758 = £1,058
2,000 " "	£300 + £1,516 = £1,816
3,000 " "	£300 + £2,274 = £2,574
4,000 " "	£300 + £3,032 = £3,332

In addition there would be a pool of £408,262 available for "inducement" payments for practice in certain areas.

If the number of principals were only 17,500 the payment per head would be ... 15s. 3d. (approx.)  
and if only 17,000 ... 15s. 4d. (approx.)

With 17,900 principals in the service, then—

If 90% of the population were on doctors' lists the rate would be ... 16s. 0d. (approx.)

The gross income (exclusive of receipts from private practice, obstetric service, mileage, etc.) would then be—

1,000 public patients	£300 + £800 = £1,100
2,000 " "	£300 + £1,600 = £1,900
3,000 " "	£300 + £2,400 = £2,700
4,000 " "	£300 + £3,200 = £3,500

If 85% of the population were on doctors' lists the rate would be ... 17s. 0d. (approx.)

The gross income (exclusive of receipts from private practice, obstetric service, mileage, etc.) would then be—

1,000 public patients	£300 + £850 = £1,150
2,000 " "	£300 + £1,700 = £2,000
3,000 " "	£300 + £2,550 = £2,850
4,000 " "	£300 + £3,400 = £3,700

And if 80% of the population were on doctors' lists the rate would be ... 18s. 0d. (approx.)

The gross income (exclusive of receipts from private practice, obstetric service, mileage, etc.) would then be—

1,000 public patients	£300 + £900 = £1,200
2,000 " "	£300 + £1,800 = £2,100
3,000 " "	£300 + £2,700 = £3,000
4,000 " "	£300 + £3,600 = £3,900

### Right of Appeal to the Courts

28. Parliament have accepted the view, embodied in the Act, that as the ultimate responsibility for the service is placed by Parliament on the Minister, it must be left to him to decide in the last resort whether it is possible for him to retain in the public service in any particular area, or even at all, a practitioner whose retention, in the Tribunal's view, "would be prejudicial to the efficiency of the service." Any other situation would be impossible. If the Minister is to be answerable to Parliament for the success of the service, he cannot be put in a position where he has to answer for a doctor whom he is forced to retain. The Minister thinks that it would help him to consult an Advisory Committee of the type which has hitherto advised on similar cases arising under the insurance scheme and provision will be made for this in regulations.

29. Nor would such a situation apply to any other profession or vocation. Of course, there is fully retained the doctors' ordinary legal rights to go to the Courts on the grounds of unlawful action by the Minister or others. Nor are the rights of the General Medical Council in any way prejudiced.

### Midwifery

30. There is no suggestion, of course, that any qualified medical practitioner should be in any way debarred from practising midwifery. The new health service is concerned with arrangements for maternity only within the service. There have been some discussions on this with general practitioners, midwives, and others, and the Minister is advised that the best arrangements to secure that the standard of attention for the expectant mother is uniformly good throughout the new service should be as follows. The hospital and specialist service will provide for specialist obstetrics and for confinements in hospitals. Otherwise all general practitioners in a local health authority's area will be asked to say whether or not they wish to practise midwifery and to answer calls by midwives for medical aid under the Midwives Act, as applied to the new service by the new Act. Any who wish to do so will be asked the extent and nature of their obstetrical practice during the preceding three years. Their particulars will be put before a local professional committee (including general practitioners, a local consulting obstetrician, and the medical

officer of health). This committee will decide on the list of local practitioners suitable for answering calls from midwives and at the same time taking part in the maternity services provided by the new Act. Others, not included in the list, will need further obstetrical experience first, and the list will be periodically reviewed.

31. Every woman will be entitled under the Act, for all ordinary purposes, to the medical advice and treatment of a general practitioner, by their mutual agreement. She will no doubt consult him in pregnancy, and, for her confinement, he will tell her how to obtain the services of a midwife under the Act; also, if he is not himself on the maternity list (above), he will tell her how to choose a doctor on the list who will look after her through her pregnancy and—if he wishes—be present at her confinement. If he is on the list he will do it himself. Maternity care will not be part of the obligatory terms of service of all general practitioners and an additional, inclusive, fee for pre-natal and post-natal care and the confinement will be payable. But it will be open to every family doctor to see his patient through her confinement if he is willing to do so.

### OTHER POINTS

#### Chairmanship of Local Executive Council

32. The Minister agrees with the Committee that, after the term of office of the first Chairmen (due to end on March 31, 1949) Executive Councils should propose their own chairmen. Practical effect can be given to this by inviting Executive Councils, when the time comes, to nominate the persons whom they want the Minister to appoint as chairmen, and the Minister can then adopt their suggestions. No practical point arises on this until after the first chairman's office has expired in 1949, and the matter will be reconsidered then.

#### Consultation with Local Units of the Profession

33. The Minister agrees that there must be maximum co-operation between the various bodies responsible for different aspects of the new health service and the local representatives of the professions taking part in it. But the consultations necessary for this are, in his view, better left to the good sense of those concerned than placed on any stereotyped or compulsory footing. It is certainly his intention that the planning and equipping of health centres, for example, should be carried out in the closest touch with local representatives of the professions—any other method would be unworkable—and particularly with those wishing to work in the centres, but it is not necessary for this purpose to incorporate any formal regulations into the Act.

34. Consultations between Executive Councils and Local Medical Committees should not be limited to occasions prescribed by regulation. Co-operation is of the very essence, and the local medical profession is strongly represented on every Executive Council under its constitution. It will be for these medical members to make sure that consultations do in fact take place on all appropriate occasions.

#### Scope and Conditions of Service

35. All the Committee's views on this are agreed, so far as affects Anaesthetics, Emergency Attendances, and Practitioners' Lists.

#### Certification

36. The effect of the Act is to require doctors to issue to their patients, without charge, certificates reasonably required under or for the purposes of any public enactment. The Minister will do his best to help the profession to comply with this obligation by publishing a list of certi-

ficates which seem to him to come within the requirement. Meanwhile, he has taken steps to have an interdepartmental Committee on Medical Certificates appointed with the object of reducing the general burden of certification on doctors, and the whole position will be reviewed as soon as this committee has reported.

### Health Centres

37. The Minister agrees that the Central Health Services Council shall have a Standing Advisory Committee, or a special subcommittee, on Health Centres. It has never been intended that any practitioner should be compelled in any way to practise in a health centre. Building limitations will delay the development of the health centre idea, which the profession itself has advocated. Lessons must be learned from experience, and all types of centre must be tried, always with the help of expert central advice and control. Doctors and other professional people participating in a centre must be free to practise their profession in their own way, and must be given all proper voice in the internal arrangements of the centre. Indeed, the whole new venture of the health centre—which, if properly conducted, should be certainly of as much interest to the profession as to the Minister—will depend upon the co-operation of the profession with the Minister in an attempt to give publicly provided facilities for the personal and family doctor and dentist to give the best possible service to his patients.

#### Assistants

38. The Minister entirely agrees with the views expressed by the Committee under this heading.

### Collective Responsibility

39. The Minister is in general agreement with the Committee's views on collective responsibility and a central fund. His more detailed proposals are set out under the heading of Remuneration, in paragraphs 26 and 27 above.

### HOSPITAL AND SPECIALIST SERVICES

#### Transfer of Hospitals

40. The Act lays on the Minister a statutory obligation to provide an adequate hospital service. If he is to be able to discharge this obligation he must clearly have transferred to him all existing hospitals which are essential for the provision of the service now, and must have powers to acquire land and premises—if necessary compulsorily—essential for the development of the service to meet future needs.

41. For the purpose of transfer, therefore, the definition of hospital must be wide enough to embrace all units—normally describable as hospitals—which are essential to the service. But the power given to the Minister to exclude hospitals from transfer shows that no absolute monopoly of hospital provision is in view, and that it is not intended to transfer such units as are not required for the new service. Each unit liable to transfer is already being given the opportunity to advance any good reasons for its exclusion. In general the Minister would regard any private nursing home, which happened to prove to be legally liable to transfer, as having *prima facie* grounds for exclusion, and would normally exclude it subject to hearing any views of the appropriate Regional Hospital Board. It is by this means, rather than by amendment of the definition in the Act, that the points raised by the Committee can best be met; and indeed any definition which could be devised would inevitably give rise to cases which could be met only by this procedure. Nursing homes run for profit are of course, not transferable at all.

42. As to the acquisition of land and premises, it would be impossible to exclude entirely from the Minister's powers the acquisition of hospitals, when the very purpose for which the powers are conferred is the provision of a hospital service. But it is also clear that the acquisition of a number of small private nursing homes would be a thoroughly uneconomic and unsatisfactory method of developing the service. It is, as a matter of common sense, only very exceptionally that any question of acquiring private or voluntary hospitals or clinics after the appointed day might be likely to arise.

43. It is hoped it will be possible early in 1948 to "disclaim" all hospitals whose transfer is not required for the service. The Minister is obtaining the views of Regional Boards, but it is with the Minister that the final decision (both in principle and in individual cases) lies.

#### Hospital Accommodation for Private Patients

44. The Minister's intention is that the allowance of treatment of private patients in any private accommodation set aside in a hospital shall extend to all practitioners who are members of hospital staffs in the service and who wish also to engage in such private practice by agreement with their patients. But it would be impracticable to lay down a definite obligation in this, since the extent to which any such arrangement is possible must depend on the local availability of facilities.

45. When treating private patients in private accommodation in a hospital, the doctor will be using facilities provided at the public expense. It therefore seems natural that reasonable limits should normally be set to the charges made to the patient for the personal benefit of the practitioner. It is intended that the limits should not be set in any way unduly low, and that there should be adjustment within the maxima to the circumstances of the patient by private arrangement between him and the doctor. In addition, however, the Minister is prepared—where circumstances make it possible—to allow a proportion of the available private beds to be used without any prescribed maximum charge. He will examine how this can best and most fairly be done.

46. It should be clear that there is a complete difference between the position of the patient in accommodation provided under Section 4 and that under Section 5 (both referred to in the Committee's statement). The former is taking advantage of the public service, and is paying only for the additional amenity of a single room or small ward. The latter has elected not to take advantage of the public service, but to seek his hospital treatment outside it.

47. Under Section 4 the only charge payable by the patient is that for the additional cost of the separate accommodation. The reference in debate to the recovery of medical fees was intended not to refer to this, but to deal with the position where no separate private pay block may exist and where any accommodation for purely private patients may therefore be set aside in certain rooms or small wards; but this would be done under Section 5 and not under Section 4.

48. The extent to which purely private pay-bed accommodation is made available and treatment of private patients in hospital allowed must clearly depend on the size of the demand and on the extent to which facilities can be provided without detriment to the main health service. The special provision made for it in the Act is, however, a clear indication of the intention that it will be made available, and that action taken under Section 4 or otherwise will not be such as to exclude private arrangements.

49. Where a pathologist or radiologist participating in the service also engages in private practice, it will be open to

him to enter into agreed arrangements for attendance on private patients in private pay-bed accommodation within prescribed maximum fees under the Act.

#### Method of Preference of Patients to Specialists

50. The Minister accepts in the main the proposals made by the Committee. It is contemplated that the patient will normally obtain specialist advice through his family doctor, who will refer him with a written statement of the case. Exceptionally, however, the patient may seek specialist treatment direct—for example, from a venereal diseases clinic. With regard to diagnostic facilities, it will be an objective of the service that reasonable facilities should be available directly to general practitioners; but the first call on hospital facilities must be to meet the needs of the hospital service, and only as they can be developed will they become more generally available.

#### Appointment of Specialists

51. It is proposed that appointments of medical staff up to and including registrars at non-teaching hospitals should be made by the Hospital Management Committees. Senior appointments, however, should be made by the Regional Boards on the advice of an appointments committee constituted according to the nature of the appointment but including in all cases representatives of the Management Committee or Committees concerned. The Minister agrees that the more exact constitution of these committees must be worked out at an early date and he proposes to do so. He also shares the view that it would be an advantage for the appointments committees for non-teaching hospital posts to include university representatives and expert assessors from other regional areas, and guidance to this effect will be given to Regional Boards.

#### General Terms of Service

52. The Minister notes the Committee's views on the method of remuneration of specialists, which he will have to consider further with the profession when he has received the report of the Spens Committee on Specialists. As to the domiciliary service, he considers that specialists should, as widely as practicable (though not universally), be expected to accept as part of their duties the undertaking of domiciliary work within defined limits. The principles proposed by the Committee for the operation of the service accord with his own views.

#### Chairmen

53. The Minister thinks that any views expressed by Boards of Governors and Management Committees about the succession to the chairmanship should clearly be given full weight; but their position as his direct agents in administering the service makes it essential that the final decision should lie constitutionally with the Minister in each case.

#### LOCAL HEALTH AUTHORITY SERVICES

##### Statutory Health Committee

54. It was the decision of Parliament that local health authorities, as responsible local government bodies, ought not to be dictated to on the co-optation of non-elected members on their Health Committees. The Minister has no powers of compulsion in the matter and would not wish to seek them. Nevertheless, he has encouraged—and will continue to encourage—local authorities to use the powers conferred on them to co-opt non-elected people so as to secure, among other objectives, the inclusion of representatives of the medical profession in the area. As the figures quoted by the Committee show, the majority of authorities have done so.

### Remuneration

55. The Minister agrees with the Committee. The details of future negotiating machinery are at present under discussion with the profession and all other professions concerned.

### Decentralization of Local Health Authority Services

56. The Committee is under a misapprehension here. Schemes of decentralization, as so far advocated by the Minister, cannot themselves result in depriving the county district medical officers of health of any part of their work. The Act itself—irrespective of any decentralization—governs any effect the service may have on these officers.

## MENTAL HEALTH SERVICES

### Division of Responsibility

57. The Minister fully recognizes the importance of the points raised in this paragraph and his views have been conveyed both to Regional Hospital Boards and local health authorities in the documents already issued to them.

58. In a memorandum on the mental health services issued to Regional Boards, there is the following passage:—

"It will be apparent that the efficient administration of the mental health service will depend in a crucial degree upon the effective linking of the operations of the Regional Boards on the one hand and of the local health authorities on the other."

The need for close co-operation is emphasized throughout the memorandum and several parts of it refer specifically to the possibilities of joint user of officers, including psychiatrists.

59. In a circular issued to local health authorities on the mental health services the importance is stressed of maintaining close touch with the Regional Boards and the Hospital Management Committees, and also the desirability of arranging for joint user of officers, including psychiatrists. Local health authorities have been asked to include in their proposals (which have to be submitted for approval under the Act) the extent to which they propose to arrange for the joint user of specialist medical officers of the Regional Boards.

60. As to grouping, the circular says:—

"Two or more authorities may agree arrangements for the joint user of an officer having special qualifications or experience in mental health work to act as medical adviser to their mental health service subcommittees."

### Regional Psychiatrists

61. Memoranda already issued to Regional Hospital Boards indicate the Minister's view that the Boards should appoint a mental health services committee or subcommittee and a Regional Psychiatrist. The status of the latter post, and its remuneration, have been discussed with the Mental Health Services Subcommittee of the Negotiating Committee, as a result of which the proposed scale of salary has been reconsidered. This has now been fixed at a figure which, in the Minister's opinion, should attract men of appropriate standing to fill these posts.

## SUPERANNUATION

### Provision for Added Years

62. Doctors are not alone among professional people who have a lengthy training period before entering on remunerative employment. The superannuation scheme goes a great way to meeting them by providing that a doctor will become superannuable as soon as he enters a

hospital post, which—it is hoped to secure—will include the last year of his training after qualification but before registration. For the average doctor, this will happen at about the age of 23 or 24. From then onwards his service will build up in the scheme through his various employments in hospitals, clinics, and practitioner service. He will be able to retire at 60, though if he stays on till 63 or 64 (when he will have done his forty years' service), he will get a larger pension. In comparison with, for example, the local government scheme now, he will be much better off because at present his service does not begin to count until he has taken up a local government appointment which may be after a period of practitioner service and certainly after his training hospital work and he cannot retire until he has done forty years' service or reached the age of 65.

### Immediate Cover against Incapacity or Death

63. Other public service schemes require a period of qualification before benefits are payable. In the proposed scheme it is five years for death gratuity and a gratuity on incapacity and ten years for pension on retirement on age or incapacity. The scheme requires no medical examination and it cannot take on a quite unknown liability in respect of people who may be unsound lives, without some preliminary period of service.

64. As to elderly doctors who come in at the beginning, they will get compensation for the loss of their right to sell their practices; and this represents what they would normally have expected to get, quite apart from the further benefits provided by the new scheme.

### The Suggestion that the Proposed Widow's Pension is Inadequate

65. The widow's pension is one-third of the pension which the doctor would have got had he retired on account of incapacity at the time he died. Any increase on this would have meant diminishing other benefits in the case of married doctors. Moreover, this widow's pension will be in addition to the new national insurance arrangements which after July 5 next will apply to everyone. It should be remembered that this is the first major public service scheme which has included a widow's benefit at all.

66. As to the reductions to be made where the wife is younger than the husband, no reduction at all is made where the man is under 42 or in any case where the wife is not more than two years younger. The more advanced the age of the man the greater will be the pension which he has earned and therefore the larger the amount from which the widow's pension is derived. No reduction at all is made whatever the difference in age while the widow has to look after children of school age.

### Provision for Transfer of Superannuation Rights for a Medical Officer going from Local Government to University Service

67. The local government scheme for this purpose cannot be altered in regulations made under the National Health Service Act. It is fully agreed, however, that it is a desirable object and that the earliest opportunity will be taken to import it into the local government law.

### Provision for Secretaries and Dispensers of Practitioners in the Service

68. Any such arrangement as the Committee suggest would have to apply to all such people. It would raise considerable difficulties because there must be a substantial amount of part-time service and temporary employment among these employees. To such persons a superannuation

Provided that, if the aggregate number of medical practitioners included on the appointed day in lists of medical practitioners providing general medical services, or lists of medical practitioners providing services under any provisions in force in Scotland corresponding with the foregoing provisions of this Part of this Act, falls short of seventeen thousand seven hundred, the said sum of sixty-six million pounds shall be reduced by an amount calculated by multiplying the number by which the said aggregate number falls short as aforesaid by one seventeen thousand nine hundredth part of sixty-six million pounds.

### (3) Regulations shall

(a) prescribe the manner in which and the time within which claims for compensation are to be made, and provide for determining whether any claimant has suffered loss by reason of the matters referred to in subsection (1) of this section and, if so, the extent of that loss;

(b) provide for the distribution of the said aggregate amount among the persons who have suffered such loss as aforesaid, having regard to the extent of their respective losses;

(c) prescribe the manner in which and the times at which the compensation is to be paid, and secure that, except in such circumstances as may be prescribed, it shall not be paid until the retirement or death of the medical practitioner concerned, whichever first occurs; and

(d) provide for paying out of moneys provided by Parliament interest at 2½% per annum on the amount of the compensation payable to any medical practitioner, in respect of the period from the appointed day until the time when the compensation is paid;

and before making any regulations under this subsection the Minister shall consult such organizations as may be recognized by him as representing the medical profession.

(4) For the purpose of determining the appropriate proportion of the said sum of sixty-six million pounds—

(a) the aggregate amount of the losses in respect of which compensation will be payable under this section and under the corresponding provision for Scotland, respectively, shall be calculated in such manner as the Treasury may direct; and

(b) the said sum of sixty-six million pounds or, as the case may be, the said sum as reduced in pursuance of the proviso to subsection (2) of this section shall be apportioned as between England and Wales on the one hand and Scotland on the other, having regard to the said respective aggregate losses, and the amount apportioned to England and Wales shall be the appropriate proportion of that sum for the purposes of this section.

## Association Notices

### SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1, 1948. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the first award of the Insole Scholarship of the value of £250 for research into the causes and cure of venereal disease.

#### Conditions of Award: Applications

Applications for scholarships must be made not later than Friday, April 30, 1948, on the prescribed form, a copy of which will be

supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

### SPECIAL REPRESENTATIVE MEETING

Notice is hereby given that on the requisition of the Council a Special Representative Meeting of the British Medical Association will be held in the Great Hall, B.M.A. House, London, W.C.1, on Thursday, Jan. 8, 1948, at 11 a.m. The business of the meeting is to consider recommendations of the Council relating to

(1) a statement on the Minister's reply to the Negotiating Committee's representations; and

(2) the impending plebiscite of the medical profession.

By order of the Chairman of the Representative Body,

CHARLES HILL,  
Secretary.

### CONSULTANTS AND SPECIALISTS COMMITTEE

#### REGION 16

As a result of the ballot held to fill the vacancy caused by the resignation of Dr. M. A. Snodgrass, Mr. G. T. Mowat, F.R.C.S.Ed., F.R.F.P.S., has been appointed representative of Region 16 of the Consultants' Roll on the Consultants and Specialists Committee for the remainder of the session 1947-8.

### NATIONAL ASSISTANCE BILL

A Special Committee of the Association has been appointed to consider and report to the Council on the above Bill. The object of the Bill, among others, is to "terminate the existing Poor Law and to provide in lieu thereof, for the assistance of persons in need by the National Assistance Board and by local authorities." The Bill would give power to the Minister of Health or, as respects Scotland, the Secretary of State to make regulations providing for the payment of compensation to officers who suffer loss of employment or loss or diminution of emoluments attributable to the passing of the Act. The Minister's power, however, enables him only to make regulations in respect of persons engaged in such full-time work as may be prescribed. Part-time public assistance district medical officers, whether or not they are permanent and have security of tenure, are therefore excluded.

In reply to representations made before the introduction of the Bill, the Ministry stated that it could not depart from the general principles of compensation which are being adopted in current legislation—the principle that there should be no compensation in the case of part-time officers. The Special Committee intends to pursue the matter and has requested the Minister to receive a deputation.

### Branch and Division Meetings to be Held

DUMFRIES AND GALLOWAY DIVISION.—At Cresswell Counties Maternity Hospital, Dumfries, Sunday, Dec. 21; 3.30 p.m. Dr. Robert McWhirter: The Scope of Radio-Therapy in Malignant Disease.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

County Borough Councils.—Barnsley, Gateshead.

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, WallSEND.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

## ACUTE POLIOMYELITIS

WITH SPECIAL REFERENCE TO EARLY SYMPTOMATOLOGY AND CONTACT HISTORIES

BY

DOUGLAS McALPINE, M.D., F.R.C.P.

P. H. BUXTON, M.B., B.Chir.

MICHAEL KREMER, M.D., F.R.C.P.

D. J. COWAN, M.B., B.S.

(From the Department for Nervous Diseases, Middlesex Hospital)

In the middle of August, 1947, the Middlesex Hospital offered to the London County Council a unit of 30 beds for the early treatment of cases of acute poliomyelitis. Although the diagnosis of poliomyelitis could be confirmed in only 54 of the 104 cases which were admitted up to the middle of October, sufficient points of interest arose to warrant their description. The following classification was adopted: (1) non-paralytic, 24 cases; (2) paralytic, 26; (3) polio-encephalitis, 4; (4) abortive poliomyelitis, 6; (5) incorrect diagnosis, 44.

### Early Symptomatology

*Prodromata.*—Prodromal symptoms suggesting a stage of systemic infection were present in 70% of the non-paralytic and paralytic cases. The symptoms were those that are common to certain other infections—namely, headache, a shivering feeling, malaise, a generalized muscular aching, and fever. To these were sometimes added either signs of an upper respiratory infection such as sore throat or coryza, or a gastro-intestinal upset such as nausea, vomiting, or diarrhoea. The duration of this prodromal stage varied from 14 days to a few hours. In 9 of the 10 patients who became severely paralysed, signs of invasion of the nervous system preceded the appearance of constitutional symptoms. In a few cases the history suggested the "dromedary" type of prodromata.

### Non-paralytic Form

In deciding whether a case should be classified as abortive or non-paralytic we were guided by the presence of meningeal signs and by changes in the cerebrospinal fluid, if the latter was normal, despite the presence of severe headache, the case was considered as abortive, but if in addition to these findings nystagmus was present the case was labelled as non-paralytic.

Headache was the main symptom of the meningeal stage of the disease. At the onset it may be referred to the back of the head, but more usually it is frontal in distribution and throbbing in character: it was sometimes described by patients as the worst headache they had ever experienced. Pain referred to the neck or down the back was not uncommon. All degrees of neck stiffness were met with. In a mild form this showed itself by an inability on the part both of the patient and of the examiner to approximate the chin to the chest: during this manoeuvre the patient expresses discomfort in words or by facial expression. In the course of a routine examination of the

nervous system no abnormality may be detected beyond those already mentioned. In other cases certain minor signs may be found which clearly indicate invasion of the central nervous system, but since they are not accompanied by paresis such cases should be grouped as non-paralytic. The commonest of these signs is nystagmus; this may occur in lateral or vertical fixation, and may be either of the horizontal or the rotatory type. Its disappearance in the course of convalescence signifies its relationship to the infection. Of 24 non-paralytic cases 14 showed this sign. The following may be cited as a typical example of the non-paralytic form.

*Case 52.*—L. E., a girl aged 17, was well until Oct. 5, 1947, when she felt sick and retired to bed. Next day the temperature was 99° F. (37.2° C.), the headache was worse, and she vomited three times. On Oct. 7, when seen in casualty department, apart from mild backache she had no other symptoms. She was admitted for lumbar puncture. The cerebrospinal fluid contained 35 lymphocytes and 29 polymorphs per c.mm.; protein, 40 mg. per 100 ml.

Depression or absence of one or more deep reflexes was found in a few of the non-paralytic cases, either without any evidence of paresis or with a minimal degree of weakness which passed off in the course of a day or so.

### Paralytic Form

As a general rule prodromata and meningeal signs preceded the onset of paralysis. Both our previous and recent experience of poliomyelitis confirmed the importance of severe low backache as a local sign in poliomyelitis, particularly when the lower dorsal and lumbar cord is attacked. In the majority of our cases sensory symptoms were prominent at the onset. They were confined to or more pronounced in that part of the trunk or limbs which subsequently became paralysed. Pain was a common early symptom, while tenderness of the skin and pins-and-needles or a numb sensation were occasionally present. The following case illustrates this point.

*Case 14.*—Mrs. K., aged 30, noticed soreness around the abdomen on Sept. 4, 1947; her clothes hurt her and any light touch on the skin was unpleasant. By the evening the soreness had spread to the front of both thighs. Next day the temperature was normal. She complained of severe headache and aching at the back of the neck and in her limbs and back. On the 6th the temperature was 99° F. (37.2° C.); the pain in the legs had disappeared, but her left leg was now completely useless and the right leg partially so. She was admitted to hospital on

Sept. 7; the temperature was 102° F. (38.9° C.). The following signs were noted: marked neck rigidity, horizontal nystagmus, and a severe degree of paralysis of both lower limbs with diminution of the deep reflexes. Cerebrospinal fluid showed: cells, 94 lymphocytes per c.mm.; protein, 100 mg. per 100 ml.

Muscles supplied by the same spinal segments may show a considerable variation in the extent to which they are paralysed. For example, in the upper limb the deltoid may be severely paralysed while the biceps and brachial radialis may show only a temporary and mild weakness. The extensors of the wrist may relatively escape compared with the triceps and extensors of the fingers. Similarly, the sternal portion of the sternomastoid may be more affected than the clavicular portion. Although these facts are not new, attention is drawn to them because of their diagnostic importance. Coarse fasciculation or muscular twitching, although not an uncommon early sign in children, is seldom seen in adults; it was observed in only two cases in the present series. Lastly, minor degrees of paresis are easily overlooked unless a systematic examination of the skeletal muscles is made.

*The Myelitic Form.*—This has received little mention in the classical descriptions of the disease. The clinical picture may be that of an acute dorsal myelitis, differing in no way from that due to other causes. A stage of flaccid paraplegia with extensor plantar responses, sensory loss on to the abdomen, and retention of urine is followed by a residual spastic paraplegia with minimal sensory loss. The combination of meningitis and acute myelitis with a lymphocytic pleocytosis in the cerebrospinal fluid should suggest the diagnosis, but only if other causes such as syphilis can be excluded. A partial myelitis characterized by temporary paraesthesiae and combined upper and lower motor neurone lesions is somewhat more common. The following is a typical example.

*Case 5.*—W. A., a youth aged 17, was driver's mate in a lorry which left Yorkshire bound for London on July 21, 1947. At 9 p.m. he felt a sudden dull ache in the lower part of his back: this pain passed off within an hour. At midnight he noticed a gradual onset of numbness in the left hand and the fingers, which felt dead. Within an hour the numbness had spread up to his elbow; at the same time he noticed a weakness in this limb. At 4 a.m. the following day the numbness was noticed in the toes, and within a quarter of an hour it had spread half-way up the left thigh. The leg became weak, and on getting out of the lorry he limped. At 8 a.m. there was a gradual onset of numbness in the right hand and arm, with weakness. At 10 a.m. the numbness had spread to the abdomen, lower chest, and groins. At 12 noon he was admitted to hospital. The temperature was 98.2° F. (36.8° C.). He stated that he had no headache and that he felt quite well. There was no neck rigidity. Both upper limbs were markedly weak, except abduction and flexion of the elbows. Paralysis of finger movements was complete in the left hand and partially so in the right. The triceps-jerk was absent on the left side. There was a generalized weakness of both lower limbs, left more than right. The left knee-jerk was depressed, the remaining lower-limb reflexes were exaggerated. The left plantar response was equivocal, the right flexor. There was diminution to cotton-wool and pin-prick in both hands; doubtful pin-prick and thermal loss on right side below D2. Cerebrospinal fluid: cells, 7 lymphocytes and 1 polymorph per c.mm.; protein, 30 mg. per 100 ml. On July 24 the temperature had remained normal since admission and there was good recovery in extension of left wrist, but triceps, extension of fingers, and small muscles of left hand as well as of right were still severely paralysed. Reflexes in left leg were now brisker than on right, left plantar response extensor, right flexor. On Aug. 16 he was much improved: mild residual weakness in left triceps and intrinsic muscles of both hands, left more than right, with early wasting. Left plantar response was still extensor. Sensation was now normal.

When the case was first admitted the absence of fever and meningeal signs and the prominence of sensory

symptoms suggested an acute myelitis rather than poliomyelitis. However, after 48 hours the distribution of the paresis in the arms and the greater loss of power in the quadriceps as compared with other muscle groups in the left leg established the diagnosis of poliomyelitis.

### Polio-encephalitis

Several factors account for the varied symptomatology that may occur in polio-encephalitis. First, although the virus of poliomyelitis is highly neurotropic for motor nuclear masses in the brain stem and spinal cord, it may attack other components of the nervous system. Secondly, although the brain stem is mainly affected, there is clinical and histological evidence that in polio-encephalitis higher levels of the brain may not be spared. Lastly, the relative incidence of polio-encephalitis and the signs arising from it vary considerably from epidemic to epidemic. Drowsiness may be present in the initial stages. In only one of our four cases of polio-encephalitis was it marked, although it appears to have been a prominent feature in a certain number of cases in the recent epidemic. Coma in our experience is rare. A degree of mental confusion with subsequent amnesia is not uncommon. Nystagmus is an important sign of invasion of the brain stem; it may occur alone or be associated with cranial-nerve or spinal paralyses. Pyramidal signs are not uncommon in polio-encephalitis.

There is a clinical picture which we have not previously encountered and which so far as our inquiry into the literature goes has not been reported in any previous outbreak of the disease. Some of the features of this unusual condition have been described by Strickland (1947), Marmion and Sandilands (1947), and one of us (McAlpine, 1947).

*Case 28.*—R. P., a captain in the U.S. Army aged 32, complained on Aug. 11, 1947, of mild backache, which persisted until the 21st, when he developed a headache, sore throat, and aching pains in the neck and legs. He vomited once and had mild diarrhoea. The temperature was 100° F. (37.8° C.). During the next few days he improved. Nystagmus was noticed for the first time on Aug. 25. On the 27th he was unable to raise his head because of muscle weakness and the nystagmus had increased. Next day he was admitted to hospital. The temperature was 98.8° F. (37.7° C.). He complained of backache, weakness, and blurring of vision. He was markedly euphoric, with emotional lability. His memory was good for both recent and past events; his orientation and co-operation were excellent. There were no disturbances of micturition and his sleep rhythm was normal. A slight degree of neck rigidity was noted. He showed violent jerky conjugate movements of the eyes both laterally and on elevation. There was a large rotatory element in the movements especially on lateral fixation. The slightest movements of the eyes, the act of blinking, and even an emotional stimulus would produce this phenomenon. After an object was fixed for a few seconds the ocular disturbance subsided. Occasionally, spontaneous movements would appear, though these may have been due to attempted voluntary fixation unnoticed by the observer. With the violent lateral movements a synchronous lateral tremor of the head and neck developed which was very obvious to the patient and which he could not control. The ocular movements were full and the pupils and other cranial nerves were normal except that he disliked lifting his head from the pillow. Jaw-jerk was unaffected. Power, tone, and co-ordination were normal in the limbs. In the arms the tendon reflexes were unaffected, but they were considerably exaggerated in the legs. The right plantar response was flexor, the left extensor. He had marked hyperaesthesia to stroking of the abdomen. There was no sensory loss. Cerebrospinal fluid contained 53 lymphocytes and 1 polymorph per c.mm.; protein, 80 mg. per 100 ml. The condition remained stationary for two days, and then the head movements disappeared. Both plantar responses became flexor by Sept. 2, but the eye movements were still very active, though much less so than formerly.

The euphoria was now less evident, and he continued to improve. He was transferred to an American Army hospital on Sept. 12, and still showed eye movements to the left and vertically.

Orzechowski (1927) described two forms of these spontaneous eye movements: (a) an ataxic dysmetria due to cerebellar disturbance, and (b) opsoelonia due to a lesion in the basal ganglia. Cerebellar signs, though not observed in our case, may sometimes be present. A common mechanism acting through the median longitudinal bundle may explain the synchronization of the head and eye movements, but the precise physiological basis of this unusual condition will be determined only at necropsy.

The incidence of polio-encephalitis in our series was very small, but during the recent epidemic we had the opportunity of seeing a number of cases in other hospitals in which varying degrees and combinations of cranial-nerve palsies have been present; these have not differed from those described previously in this and other countries. Details of these palsies as they occurred in cases in the London area will shortly be published by Sir Allen Daley.

Of the early symptoms of bulbar palsy, difficulty in swallowing and in talking are the commonest. In the following case stridor was the presenting symptom; other atypical features were the relative absence of fever and of changes in the cerebrospinal fluid.

*Case 53.*—R. A., a girl aged 17, was well until Nov. 5, when she developed a headache which had disappeared by the evening. Next day she woke up with a cough, which worsened during the morning. About noon she found great difficulty in getting her breath. She was seen in the casualty department and was admitted to the E.N.T. department at once, where on laryngoscopic examination Mr. J. P. Monkhouse found a complete bilateral abductor paralysis. When seen at 3.30 p.m. by one of us her temperature was 99° F. (37.2° C.), pulse 106. There was a marked degree of dyspnoea with inspiratory stridor. The voice was feeble and husky and she had difficulty in swallowing. The palate was paretic. Both sternomastoids and trapezii were weak. The tongue could not be protruded beyond the line of the teeth. The limbs were normal. At 4.30 p.m. tracheotomy was performed. On Nov. 7 the temperature was normal. She complained of numbness of both hands, but no weakness could be detected. Nystagmus was now present. Palate and tongue movements had slightly improved; swallowing was less difficult. Further improvement was noted on the 8th. Cerebrospinal fluid showed: 1 polymorph per c.mm.; protein, 25 mg. per 100 ml. She continued to improve, and on Nov. 21 the tracheotomy wound was closed. Speech was normal apart from a mild nasal quality, and she no longer had difficulty in breathing and swallowing. There remained a mild residual paresis of the palate and of the abductors.

This case illustrates the value of tracheotomy as a life-saving measure in the bulbar form of the disease.

### Cerebrospinal Fluid

The majority of our cases showed changes in the cerebrospinal fluid typical of poliomyelitis—namely, a moderate pleocytosis with a slight increase in the protein content. However, in eight out of the 30 cases of poliomyelitis and polio-encephalitis the cell count was less than 10 per c.mm. The average interval between the appearance of meningeal signs and lumbar puncture in these cases was four days. A normal cell count during the febrile stage of the disease may occasionally be met with. It occurred in approximately 5% of Service cases of poliomyelitis in the Middle East and India between 1941 and 1945. A high protein figure may be seen during the first two or three days of the illness, but is more frequent after the first week; it is usually accompanied by a pleocytosis, but occasionally may occur independently of it as in two of our cases. In three cases the protein exceeded 100 mg. per 100 ml. In one of these the fluid was examined on

the eighth day after the appearance of meningeal signs; the cell count was 12 lymphocytes per c.mm., and the protein was 180 mg. per 100 ml. This dissociation between cell count and protein increase has previously been recorded in poliomyelitis, although it is best known in connexion with acute toxic or febrile polyneuritis (Guillain-Barré syndrome).

### Differential Diagnosis

The corrected diagnosis in 44 cases admitted as acute poliomyelitis was as follows: tuberculous meningitis, 3; pyogenic meningitis, 2; tonsillitis, 10; pneumonia, 6; typhoid fever, 2; gastro-enteritis, 2; various neurological conditions, 7; miscellaneous, 12.

*Tuberculous Meningitis.*—Acute poliomyelitis usually attacks individuals in good general health and the prodromal symptoms are of short duration, whereas in a typical case of tuberculous meningitis indefinite symptoms have been present for more than two weeks. A lymphocytic pleocytosis and an increase in the protein of the cerebrospinal fluid are characteristic of both conditions. The estimation of chlorides in the early stage of tuberculous meningitis may occasionally show a figure only slightly below normal—i.e., about 700 mg. per 100 ml. The characteristic fall in chlorides may be delayed and be obtained only if specimens are examined over a week or two (Smith and Daniel, 1947). Lastly, despite modern methods of staining, the tubercle bacillus may be overlooked unless a prolonged search is made. However, in practice this difficulty in diagnosis is only likely to arise initially, since the course of the illness and the continuation of fever for more than a week should suggest tuberculous meningitis rather than poliomyelitis.

*Pyogenic Meningitis.*—The clinical picture in the early stages of a pyogenic meningitis and of poliomyelitis may be indistinguishable except that as a rule in the former rigors may occur and pyrexia tends to be more pronounced. It is essential that lumbar puncture should be carried out at the earliest possible moment in every case presenting meningeal signs. The general similarity between these two conditions is exemplified by the following case admitted as polio-encephalitis.

Mrs. R. J., aged 36, was well until Aug. 19, when she had severe abdominal pain. She had a miscarriage of twin foetuses 13 weeks old on Aug. 10, but she felt quite well the next day and got out of bed on the 12th. For the next two days she remained in bed with severe backache. On the 15th she was unable to walk upstairs owing to weakness and giddiness, and on the following day her legs were weak and she had occipital headache. On the 17th the temperature was 103° F. (39.4° C.). She had several rigors and vomited on taking solids or fluids. On the 18th she had a rapid onset of deafness. Next day she felt better but complained of marked weakness in the back and legs. On Aug. 22 she was admitted to hospital. The temperature was subnormal and she appeared collapsed, dehydrated, and stuporous. Neck rigidity was marked. Among the positive findings were nystagmus, an exaggerated jaw-jerk, and deafness, which subsequently proved to be of the nerve type. Both plantar responses were extensor. Other findings were auricular fibrillation and mitral stenosis. Blood pressure was 110/80 and there were signs of consolidation of both bases. A diagnosis of pneumococcal meningo-encephalitis was made. Cerebrospinal fluid was purulent: 14,000 cells per c.mm. (96% polymorphs). Culture grew pneumococci. Pneumococci were also grown from the blood and sputum. This patient eventually recovered after systemic and intrathecal penicillin, intravenous sulphamezathine, and digitalization. Recovery of hearing was an impressive feature in the early stages of treatment.

*Acute Benign Lymphocytic Meningitis.*—There can be no doubt that in this country a form of benign or aseptic meningitis exists which is caused by one or more strains of a virus differing from that originally described by

Armstrong and Lillie (MacCallum, Findlay, and Scott, 1939). Further, it must be realized that this form of virus meningitis may appear in epidemic form. Nevertheless, we are not convinced that up to the present time this condition has been at all common in this country, although it should be added that many cases were seen in Service personnel in the Middle East during the late war. The symptomatology is so similar to that seen in the prodromal and meningitic stages of poliomyelitis that no separate description is called for. Involvement of the central nervous system is rare in benign lymphocytic meningitis. The degree of pleocytosis in the cerebrospinal fluid is, as a general rule, greater than in poliomyelitis, counts of over 500 cells being not uncommon. As in poliomyelitis, polymorphs may predominate initially. Of the other conditions complicated by a lymphocytic meningitis only mumps and glandular fever (mononucleosis) may be mentioned. In both conditions signs of an encephalitis may rarely accompany those of meningitis. In glandular fever the enlargement of glands, the course of the illness, and the result of a Paul-Bunnell test should suggest the diagnosis.

**Epidemic and Other Forms of Encephalitis.**—Epidemic or lethargic encephalitis has not occurred in epidemic form in this country for over 20 years. Sporadic cases are seldom recognized in the acute stage, the diagnosis being made in retrospect in a case of Parkinsonism. It may be difficult to classify a case of encephalitis showing drowsiness and ocular paresis unless other cranial-nerve or spinal palsies are present. As to the other forms of encephalitis which may occur in this country, precise knowledge is lacking not only of their incidence but also of the viruses responsible for them, but it would appear that such cases are comparatively uncommon. Now that the virus of acute poliomyelitis is well established in Great Britain it should be assumed that it is the usual cause of brain-stem encephalitis accompanied by signs of meningitis unless there is good proof to the contrary. The majority of the cases of meningo-encephalitis which occurred in the London area in 1946, and which were attributed by Jennings (1947) and more recently by Laurent (1947) to an unknown virus, appear to have been similar in most respects to those seen in the recent epidemic of poliomyelitis. In Jennings's series 22 patients showed signs of meningitis or of a meningo-encephalitis. Cranial-nerve palsies and/or pyramidal signs were relatively common. With one exception the cell count in the cerebrospinal fluid was increased. In 13 "influenzal" or "non-meningitic" cases headache and slight stiffness of the neck were the chief features of a brief febrile illness. The cerebrospinal fluid in these cases was normal. These appear to have been abortive cases of poliomyelitis.

#### Contact Histories

Since the work of Wickman (1907) it has become increasingly clear that abortive cases of poliomyelitis and healthy carriers of the virus are of more importance in the spread of the disease than the paralytic case. Reference has already been made to the symptomatology of the abortive case, which differs little from the prodromata of the disease itself except that catarrhal or intestinal symptoms may constitute the whole illness. The significance of minor illnesses preceding or accompanying an outbreak of poliomyelitis can be firmly established only by proving or disproving the existence of the virus in the pharynx or faeces of such patients by means of a passage to monkeys or cotton-rats. Unfortunately, facilities in this country for this type of work are at present extremely limited.

In an attempt to determine a possible source of infection patients and relatives were carefully questioned concerning

the occurrence of minor illnesses in the family, at school, and among friends or fellow workers. In 19 of 54 paralytic and non-paralytic cases a positive history was obtained. In five cases symptoms were those of an upper respiratory or intestinal infection. In the remaining 14 cases constitutional symptoms were followed by headache severe enough to suggest a mild meningitis. Eight of these were admitted to the Middlesex or some other hospital as suspect cases of poliomyelitis; in three of them there was a pleocytosis in the cerebrospinal fluid.

The following is an example of minor illnesses, suggestive of abortive attacks, in a family of which one member suffered from a non-paralytic form of the disease.

**Case 50.**—R. J. W., aged 11½. Between July 22 and 29, 1947, he suffered from sore throat, mild headache, and fever. At the beginning of August he was apparently well, though pettish, but on the 16th he was again unwell and feverish for a day. He complained of aching in the shoulders on the 23rd, and on the following day of stiffness in the neck. On the afternoon of the 24th his temperature was 101° F. (38.3° C.). Next day the shoulder-ache was no longer present, but he had mild headache, and was admitted to hospital; temperature normal. The only abnormal sign was a mild degree of neck stiffness. The cerebrospinal fluid showed 28 lymphocytes per c.mm.; protein, 30 mg. per 100 ml. The patient had one brother and two sisters, aged 10, 7, and 4 respectively. Between Aug. 7 and 12 both sisters were in bed with a temperature of 102° F. (38.9° C.). The elder girl had headache; the younger had no headache, and fever lasted only one day. Between Aug. 17 and 20 the elder girl had a recurrence of headache and complained of stiffness of the neck; a temperature of 100° F. (37.8° C.) was recorded on one of these days. The father had fever and headache between Aug. 13 and 16. The charwoman's child, aged 8, a contact of the children, was unwell with fever between the 14th and 21st. The mother stated that several other children in the same road, as well as their parents, had "stomach-aches and slight fever" about this time.

The following family history is of interest as it would seem possible that the mother and son were both infected by the daughter.

**Case 2.**—Miss A. L., aged 24, and her mother were on holiday at the seaside from Aug. 18 to 25. Her brother (Case 1) and her father remained at home in London. On the 18th Miss A. L. suffered from diarrhoea and backache, which lasted for 36 hours. On her return to London (Aug. 25) she complained of aching pain in the lower part of the back and both loins; she was drowsy and slightly jaundiced. The temperature was normal. These symptoms lessened over the next few days. On Sept. 3 a "rheumatic" type of pain in the back spread to the right shoulder and down to the hips, followed next day by headache. On the 8th she noticed stiffness of the left leg on getting out of bed, and on the following day there was weakness of both legs. On admission to hospital on the 11th she showed signs of mild paralysis in the lower limbs. On Aug. 25 her mother "felt rotten" and had fever for one day only.

**Case 1.**—M. L., aged 21, brother of Case 2. On Aug. 30, five days after his mother's and sister's return from holiday, he complained of pain across the chest, backache, and abdominal discomfort. Temperature was 100° F. (37.8° C.). A mild degree of jaundice was present. By Sept. 4 he felt better, but the next day he noticed stiffness of the neck, slight sore throat, followed in a few hours by severe headache and profuse sweating. On the 6th he felt a dull ache in the back and both legs. Headache had disappeared by the 9th, but his neck was still stiff and for the first time he noticed weakness in both arms and legs. On admission on Sept. 11 a mild degree of paralysis in the left arm and both legs was noted.

Examples of two nurses contracting the disease from patients they had nursed have previously been given (McAlpine, 1945). One of our cases is also interesting in this connexion.

**Case 5.**—This patient (W. A.) was in all probability the source of infection in a nurse. The diagnosis of poliomyelitis was not

made until 48 hours after his admission; during this period he was nursed without precautions. Nurse B. C. nursed him from the day of his admission (July 21) to July 25. Three days later she had a dental extraction but was well until the 29th, when she complained of pain behind the sternum and of a slight aching pain in the left wrist. On July 31 the headache was marked: temperature 100° F. (37.8° C.); cerebrospinal fluid: 18 lymphocytes and 1 polymorph per c.mm.; protein, 30 mg. per 100 ml. Slight weakness of extensors of wrist and fingers of left hand was noted on Aug. 1.

Nothing is known of the factors that render a person susceptible to an attack of poliomyelitis. The concept that immunity to the disease is conferred in childhood by a subinfective dose of the virus is not entirely borne out by recent facts (Van Riper, 1947). Sabin (1947) has pointed out that there is evidence to suggest that there may be no relationship between an attack of the disease or the passing of an epidemic through a community and the appearance of a neutralizing antibody as tested for against a single standard strain of virus, and occasionally even against some more recently isolated strains. Burnet and Jackson (1939) have stated that poliomyelitis antibody is not a result of exposure to or infection by the virus of epidemic poliomyelitis. During the past quarter-century there has been a definite rise in the age incidence of the disease in all poliomyelitis countries. Furthermore, the disease and the mortality rate have both been more severe in adolescence and in adults than in children. Such information as is available about the recent epidemic in this country would seem to confirm this tendency. One of our cases—a doctor's wife—apparently passed the infection to her brother-in-law, aged 30, but failed to infect her own two children, with whom she was in much closer contact, despite the fact that one, aged 3, had had a dental extraction during the time she showed prodromal symptoms and the other child, aged 5, had had a tonsillectomy a few days before.

Two of our cases gave a previous history of close contact with poliomyelitis in the early febrile and paralytic stages of the disease, yet both cases remained well at that time but contracted the disease in the recent epidemic.

**Case 23.**—Mrs. C., aged 21. During September, 1938, when 12 years of age, she was on holiday and sharing a bed with her sister. The sister developed headache, high temperature, and general malaise, followed by severe paralysis of her right leg. A diagnosis of poliomyelitis was made. Mrs. C. continued to share her sister's bed until the latter was removed to hospital. She herself remained perfectly well, but contracted a mild attack of poliomyelitis on Sept. 2, 1947.

**Case 28.**—Captain R. P., aged 32. In 1945 in Washington, U.S.A., he shared a room with another man, aged 28, who developed headache, aching all over, and stiff neck, followed by paralysis of the small muscles of his right hand. He was removed to hospital as a case of acute poliomyelitis. For two days he was fed and cared for by Captain R. P., who remained well at that time but contracted polio-encephalitis on Aug. 21, 1947.

Thus it would seem that if a child or an adult is exposed to the virus and does not develop paralysis, immunity either may not occur or may be short-lived. Judging by recent reports, second attacks of the disease are not so rare as were formerly supposed. In Alves and Pugh's (1947) case eight and a half years elapsed between the attacks. The three examples recently reported by Lipscomb (1947) concerned officers in India. In one of these the second attack occurred within six months of the first. A similar short interval was recorded by Cunningham (1947). Variations in the strains and virulence of the virus may in part explain second attacks of poliomyelitis, although it is possible that unknown factors underlying susceptibility may be of equal importance.

## Summary

Symptomatology in 54 cases of acute poliomyelitis is discussed—24 of the cases belonged to the non-paralytic form. There were no deaths.

Several case histories are given, including an example of a rare ocular complication (opsoclonia), as well as an unusual case of bulbar paralysis successfully treated by tracheotomy.

Attention is drawn to certain atypical features in the cerebrospinal fluid.

In nearly one-third of the proved cases contact histories suggested the probability of an abortive attack of the disease in other members of the family or in friends.

In this country the virus of acute poliomyelitis should now be regarded as the usual cause of a benign type of lymphocytic meningitis and of a brain-stem encephalitis accompanied by meningitis.

A brief reference is made to the problem of immunity.

# POLIOMYELITIS

## THE PRE-PARALYTIC STAGE, AND THE EFFECT OF PHYSICAL ACTIVITY ON THE SEVERITY OF PARALYSIS

BY

W. RITCHIE RUSSELL, M.D., F.R.C.P.  
Neurologist to the Radcliffe Infirmary, Oxford

### [PRELIMINARY REPORT]

The current epidemic of poliomyelitis provides an opportunity of studying the clinical features of this disease which is fortunately seldom available in this country. Though a great variety of symptoms have been reported in the present epidemic (Kelleher, 1947) many students of other epidemics have insisted that the pre-paralytic symptoms and signs in poliomyelitis are specific, and that it is possible to diagnose the disease before paralysis develops (Kauders, 1938; Gordon, 1932; Aycock and Luther, 1928; Adamson and Dubo, 1942).

A history of great physical exertion preceding the onset of severe paralysis has often evoked comment in cases of poliomyelitis (de Rudder and Peterson, 1938; Tucker, 1941), but no attempt (so far as I am aware) has been made to investigate this aspect of the problem statistically.

It is generally agreed that a study of the pre-paralytic symptoms gives no clue to whether or not paralysis will develop. Further, the changes in the cerebrospinal fluid in the pre-paralytic stage are equally abnormal whether or not paralysis subsequently develops (Collier, 1927; Adamson and Dubo, 1942).

It is not surprising, therefore, that in recent years attention has been directed to the physiological state of the

lower motor neurone in relation to its susceptibility to the virus (Rivers, 1942).

A striking phenomenon in this connexion has been that if the anterior horn cell is engaged in regenerating its neurone—that is to say, if the peripheral nerve originating in these cells has been sectioned a few days previously—then these anterior horn cells are quite immune to experimental infection with the virus (Howe and Bodian, 1942). It is by no means impossible, therefore, that physical activity at a certain stage of the disease might alter the motor neurone physiology in such a way as to influence its vulnerability to the virus.

The present investigation aimed at analysing the early symptoms and physical activity in a group of patients convalescent from poliomyelitis who were old enough to give an accurate account of their symptoms, and at comparing the various clinical features of the disease with the degree and site of paralysis. The scheme used for recording the main facts (see Form) provides a convenient method for recording the pattern of the disease. All the cases except five occurred during 1947 in this country. To ensure uniformity all case records were made by me.

\* With the aid of a calendar most patients were able to describe with remarkable clarity their symptoms on the days preceding paralysis. Lest the features of the disease might vary in different regions cases were seen in various parts of the country, including Oxford, London, Edinburgh, and Manchester.

Meningitic Symptoms

The so-called meningitic-symptoms in the pre-paralytic stage are of special importance, for it is only by the study of these that one can hope to diagnose poliomyelitis before paralysis develops. These symptoms may, however, present in widely differing ways, and they vary greatly in severity. At first the meningitic symptoms may be slight and appeal to the patient to precede the real onset of the disease. Again, severe pains may occur, say, in the thighs for a few hours only, and may be followed by a period of perhaps 24 hours in which he feels quite well.

For the purpose of the present analysis meningitic symptoms were taken to include all those which caused pain in the head, spine, trunk, or thighs; a general feeling of aching all over was not included.

There is no doubt that in some cases the patient feels unwell before the meningitic symptoms develop; but, as the meningitic symptoms are so important for diagnosis, in this study Day 1 of the disease is taken as the day on which the first meningitic symptoms appear. In Table I the relation between the onset of meningitic symptoms at P and the appearance of paralysis at P is clearly shown. It is evident that in the majority of cases the meningitic symptoms precede paralysis by three or more days. The detailed analysis and correlation of symptoms, site of paralysis, etc., must wait for a later study.

The so-called meningitic symptoms often suggest nerve root irritation and may indicate that the virus travelling up the peripheral nerves has reached the vicinity of the meninges. Experimentally, the virus travels up the peripheral nerve at 2 to 3 mm. per hour (Howe and Bodian 1942), and does not reach the spinal cord until the day preceding paralysis (Bodian and Cumberland, 1947). Another misleading feature of the pre-paralytic stage is that prior to the onset of paralysis the patient's symptoms often become less severe; he feels better, and may think that his illness is passing.

Meningitic symptoms appeared in the pre-paralytic stage in all but one case (No. 22) of this series. The initial site of meningitic pain was as follows: back of the neck, or subjective neck stiffness, 11 cases; dorsal spine or scapula region, 5 cases; lumbar spine, 5 cases; sacral spine, 4 cases; chest (bilateral), 6 cases; one or both thighs, 2 cases; head (frontal or general), 10 cases. In most cases two, three, or more of these symptoms developed during the pre-paralytic

TABLE I.—Record of physical activity in the pre-paralytic stages in 44 cases of poliomyelitis. The † in Day 1 indicates the onset of the first meningitic symptom, and P gives the onset of paralysis. The footnote gives the method used for scoring the amount of physical activity and the severity of paralysis.

44	M	16	++	++	↑	↑	++	++	++	++	+	P						Respirator on Day 9	Very severe

Physical activity scores for each 24-hour period.—Nil = In bed. ± = Not more than 1/4 day light work—e.g., resting in house with a short walk. + = Average light work—e.g., secretarial, housework, school. ++ = Average or heavy manual work, factory or labourer or school with football or other athletic sports. (In Table III where physical activity for a period of more than 24 hours is recorded the scores for the days concerned are added together.)

Paralysis Grading.—Nil: no paralysis even temporary. Slight: no severe paralysis anywhere at any time—full recovery expected. Moderate: multiple moderate paralysis or severe paralysis of a few muscles in one limb. Severe: bilateral severe paralysis at any level including trunk, or gross paralysis of one limb. Very severe: severe and extensive paralysis such as trunk and both lower limbs or severe paralysis of all four limbs.

stage. For example, in the cases which presented with head pain, other symptoms developed as follows:

- Case 6: 24 hours later, pain in both thighs.  
 " 13: 12 " " neck stiffness.  
 " 16: 48 " " neck and shoulder pain.  
 " 17: 24 " " neck stiffness.  
 " 27: 48 " " lumbar pain.  
 " 28: 12 " " neck and back pain.  
 " 35: 12 " " neck pain.  
 " 39: No other symptom noticed till paralysis developed.  
 " 42: 24 hours later, neck pain and stiffness.  
 " 43: " " " neck stiffness.

The cases which presented with chest pain developed other symptoms rather late:

- Case 10: 72 hours later, pain in back.  
 " 18: " " " lumbar pain.  
 " 21: 48 " " sacral pain.  
 " 34: 24 " " headache and, 12 hours later, sacral pain.  
 " 41: 4 days later, lumbar pain.  
 " 44: 3 " " headache.

The chest pain reported in six cases is of special interest as its characteristics resemble closely the chest pain of epidemic myalgia (Bornholm disease). This pain is usually bilateral and referred to the lower half of the thorax; it is aggravated by a deep breath and often associated with, and indeed may consist chiefly in, a hyperaesthesia with tenderness on pressure over the lower chest.

It is clear, therefore, that though a variety of initial symptoms may be observed, the vast majority of cases

show meningitic symptoms by the time they are seen by their doctor—say within 24 or 36 hours of the onset of the pre-paralytic stage. I have not observed in this series the signs on examination at this stage, but it may be emphasized that neck and spinal rigidity are the most important signs. There may also be slight jerky movements of the limbs or eyes, while examination of the cerebrospinal fluid is of great value in confirming the diagnosis. A misleading feature may be that the patient both looks and feels well, and may have little or no fever. For example, a patient with severe neck pain when seen at a hospital out-patient department was told to return next day for an x-ray examination of his neck: 24 hours later he developed extensive paralysis. Another example is that of a young woman who, owing to severe lumbar pain, was thought to have kidney disease: within 12 hours she was almost totally paralysed, and was kept alive by a respirator. A remarkable feature of many of these cases is that when the initial symptoms have developed the patients do not feel ill. It is clear, however, that when the patient is old enough to describe his symptoms an analysis of these, combined with signs due to rigidity of the spine, gives a fairly specific clinical picture in most cases of poliomyelitis. These cases then require only examination of the cerebrospinal fluid for confirmation and in order that meningitis may be excluded.

#### Physical Activity and Paralysis

In the course of this study it soon became apparent that the patient's activity during the pre-paralytic phase varied to a remarkable degree. This seemed to be due to the fact

that the early "meningitic" symptoms are often of insufficient severity to force the patient to go to bed or indeed even to modify his routine work. It is clearly desirable that the information available regarding the degree of physical activity should be correlated with the severity of paralysis in such a way that the figures can be handled statistically.

Tables II and III relate the degree of paralysis to the amount of physical activity during the 24 and 48 hours following the onset. I am greatly indebted to Dr. R. B. Fisher for the further analysis of this material.

### Statistical Analysis

The number of cases in this survey is too small to warrant a detailed analysis, so that attention is best directed to broad classifications and practical conclusions. The paralysis gradings have therefore been grouped into the two classes of (a) patients in whom full recovery is likely (*nil* and *slight*), and (b) those in whom some residual impairment is likely (*moderate*, *severe*, and *very severe*).

Using these broad classifications, it was first shown that the history of exercise before the onset of meningitic symptoms has little bearing on the prognosis. Four patients are excluded from this analysis—two because of the vagueness of the history of meningitic symptoms (Nos. 22 and 39), one because of doubt concerning the degree of activity before meningitic symptoms (No. 12), and one because the short interval between meningitic symptoms and paralysis precluded inclusion in the later stages of the analysis (No. 24).

All the remaining 40 patients were up and about on the day before meningitic symptoms appeared, and all but three were engaged in their ordinary activities. Separating them into lighter ( $\pm$  and  $+$ ) and heavier exercise ( $++$ ), we get the following association between exercise in the day preceding meningitic symptoms and severity of the disease:

	Lighter Exercise	Heavier Exercise
Full recovery expected	16	4
Residual impairment expected	11	9

Although the proportion more severely affected is greater in the heavier exercise group, there is such a high probability (0.1–0.2) of obtaining as great (or greater) a difference by chance in sampling from a population in which there was no association between exercise and prognosis that we may say there is no significant effect of exercise, in this time period, on prognosis.

If, however, we examine the effect of exercise after the appearance of meningitic symptoms the findings are very different. Bringing in Case 12, which can no longer be validly excluded, and dividing the patients into those in bed and those indulging in any degree of normal activity, we have for the first 24 hours after the onset of meningitic symptoms:

	Rest	Exercise
Full recovery expected	10	10
Residual impairment expected	1	20

The probability of getting such an extreme distribution by chance is less than 1 in 800, so that one can be confident that complete rest in bed in this period has a profound effect on prognosis. All patients taking to bed at this time remained there for the course of the illness, so that the effect observed is of exercise starting in the 24 hours succeeding the onset of the meningitic symptoms.

The data provide one more answer of direct importance. If we exclude the 11 patients who were in bed in the first 24 hours after meningitic symptoms, and examine the effect of rest starting in the second 24 hours, we have the distribution:

	Rest	Exercise
Full recovery expected	8	2
Residual impairment expected	2	18

and the chance of obtaining so extreme a distribution by chance is a little less than 1 in 3,000.

Thus over all we find, differentiating from the remainder those patients in whom rest in bed is instituted in either the first or the second 24 hours after the onset of meningitic symptoms, the distribution of cases by prognosis to be as follows:

	Rest	Exercise
Full recovery expected	18	2
Residual impairment expected	3	19

This distribution is even more striking than in the preceding two sets of figures; and, in fact, the figures understate the influence of exercise, since two of the cases in the lower left quadrant of the table fall into the "moderate" classification of paralysis, whereas all but one of the 15 cases in the "severe" and "very severe" categories of paralysis fall in the lower right quadrant.

These data, therefore, show quite unequivocally that, irrespective of exercise before the appearance of meningitic symptoms, institution of rest in bed as early as possible after these symptoms have appeared has a profound effect on the course of the disease.

It is difficult from analysis of this material to evade the conclusion that *physical activity in the pre-paralytic stage of the disease gravely reduces the resistance of the spinal cord cells to the virus and should therefore be avoided at all costs.*

Excessive physical activity has for long been suspected as an aggravating factor, but the present study suggests that relatively minor degrees of physical activity are also dangerous. The psychological study of those who develop severe paralysis would be of interest, for it has been said that during an epidemic the disease affects "the best child in a family," who may also be the most courageous or stoical and continues physical activity without complaint after the first meningeal symptoms have developed. Certainly the severe cases of paralysis in the present series furnish many tragic records of courage and determination to continue work or play after symptoms began. The worst cases in this series are all those which required an artificial respirator owing to respiratory paralysis. The persistence in normal activity after the first meningitic symptom is a striking feature of every one of these cases.

**Case 9.**—A paratrooper aged 19. *Day 1:* From 11 p.m. the previous evening to 2 a.m. there was severe lumbar pain which kept him awake; he kept moving restlessly to change his position. On getting up in the morning he felt shivery and had little appetite. Heavy training manoeuvres as usual during the day. Slept well that night—no return of lumbar pain was noticed. *Day 2:* He does not remember pain, but had some difficulty in getting down to fasten his boots in the morning. He still had little appetite and felt shivery. During the morning he took part in heavy infantry manoeuvres and carried machine-guns up a hill. By 2.30 p.m. his legs began to feel weak and he noticed lumbar pain. By evening both lower limbs and right arm were completely paralysed. *Day 3:* The paralysis spread to his trunk muscles; there was some vomiting. *Day 4:* Respiration failed—respirator required. Six weeks later he was still in the respirator and there was little recovery in his muscles.

**Case 29.**—A female factory-worker aged 21. *Day 1:* Wakened with pain in the neck, back, and head. She worked all day in the factory, and the journey to work involved travelling for an hour each way. She vomited and noticed something peculiar about her eyes; she thought she might be getting infantile paralysis. *Day 2:* After sleeping well she still had pain in the neck, back, and head. She got up and walked (15 minutes) to see her doctor, who told her she had a chill, so she returned home, went to bed, and took castor oil. *Day 3:* The pains were less severe. She remained in bed and felt rather better. In the evening some friends called and she sat up in bed talking to them for four hours (6 to 10 p.m.). Within an hour of her friends' leaving she noticed weakness of her limbs. *Day 4:* By early morning she was totally paralysed, her respirations were failing, and when she reached hospital she was severely cyanosed and was at once placed in a respirator. Ten weeks later there was very little recovery, and she was still unable to breathe without the respirator.

**Case 31.**—Female aged 22; taken ill overseas while serving in the W.R.N.S. in 1944. *Day 1:* Wakened with a very severe sacral pain which spread into both thighs—the worst pain she has ever experienced. Otherwise she felt fairly well and worked all day at the office. While at work the pain was so severe that she could not refrain from groaning. In the evening the pain

was still severe, but she went out to a dinner party. She returned to her billet at 10 p.m., but the pain was of such a nature that she could not lie down in comfort, so she sat at a table all night, getting up to walk about from time to time to ease the pain. Day 2: She reported sick after this sleepless night, and was sent to hospital. She was able to walk to the ambulance, and to put herself to bed in hospital. During the afternoon and evening she developed complete paralysis of her lower limbs and trunk; she was put in a respirator, which was required for five weeks. Three years later there was no recovery in the lower limbs or trunk; the upper limbs were normal.

Case 32.—A female aged 20; taken ill shortly after arriving in Egypt. Day 1: Wakened with severe pain in both scapular regions. Spent the day shopping and looking round Cairo. Day 2: After sleeping well the severe shoulder pain was still present and headache developed. She continued her normal activities and enjoyed a large lunch. During the morning she ate a large number of fresh dates. She rested in the afternoon, as her pain and headache were very severe, but at night she helped to entertain friends to dinner and games. She was able to eat a good dinner, but her pain and headache were severe and it was a "frightful strain" to appear well to her guests. She vomited that evening, but was able to sleep. Day 3: She remained in bed but was very restless. Severe pain in her back developed and her temperature was raised. She slept well that night. Day 4: The pain was not quite so severe, and she was able to walk to the ambulance which took her to hospital. During the afternoon complete paralysis quickly developed in all limbs and trunk, her respiratory muscles failed, and by evening she was put in a respirator. A year later very little recovery had occurred, and the respirator was still required at night to enable her to sleep.

Case 38.—A mechanic aged 20; taken ill in August, 1946. He subsequently said that he would ignore a pain unless it was severe. He had been training for football every evening after his day's work. Day 1: While coming off the football field he caught his back while going under an iron bar. This minor injury "hurt him much more than it should"—so much so that after training for a further five minutes he went home. The back pain continued, but otherwise he felt well and had a good night. Day 2: The pain and back stiffness continued. He tried to get out his motor-cycle to go to work, but found it too heavy, so stayed at home. In the evening he walked (five minutes) to see his doctor. He slept well that night. Day 3: He was so stiff that he could not bend to tie his shoes, but he again walked to see his doctor in the morning, and then lay on his bed for most of the day. Day 4: The pains were worse, and were now very severe in his neck and had spread to all his limbs. His appetite was poor and he vomited. During this day severe paralysis developed quickly in all his limbs and trunk. He did not feel very ill, and was propped up in bed at home. Day 5: He developed difficulty in swallowing, retention of urine, and some vomiting. Day 6: His headache and pains ceased, but breathing was difficult. Day 9: He was put in a respirator, where he remained for six weeks. Fourteen months later there was still severe paralysis of all four limbs and trunk.

Case 40.—A housewife aged 33. The day before the first meningeal symptom she did a heavy day's work. Day 1: Normal housework, but by evening noticed a dull ache in her back which made her want to bend backwards. There was also pain in the head and thighs. It was difficult to get comfortable in bed, but she got relief from a pillow under the small of her back and slept well. Day 2: She awoke with severe pain in the back and scapular region, and less severe pain in both thighs. She felt stiff and could only move slowly. She debated with herself whether to leave her husband and family to get their own meals, but thought it "a bit mean" and struggled on. She hates "to be beaten by anything." She therefore fed her baby and cooked the meals, but this was a great struggle, and she sat about the house restlessly trying to find ease for her back, and trying one chair after another. During the day she took about 12 tablets of codeine co., which helped her headache but gave little relief to the pains in her back and limbs. That night she got little sleep and restlessly changed her position in an attempt to get relief. Day 3: Her back and limbs were less painful, but she had no desire to

eat and felt feverish. She remained in bed most of the day, sleepless and restless. During the evening her thighs and trunk felt a little weak. That night she was again restless and sleepless. Day 4: After a bad night she called in her doctor for the first time. She was now aching all over, with high fever and vomiting, but the pain in the back was much less and occurred only on movement. During the day there developed severe paralysis of the trunk and lower limbs. On the sixth day the paralysis rapidly spread to the upper limbs. She was admitted to hospital on the seventh day and had to be put in a respirator at once, as her breathing had failed.

Case 44: A schoolboy aged 16. Day 1: Developed a feeling of constriction in his chest, which he felt specially on taking a deep breath. He also had slight pain in the right groin. He attended school, and in the evening he ran in a 100-yards race. Day 2: Symptoms unchanged, but in the evening he had a stiff feeling on bending. He felt well, sat examinations, and played a hard rackets match, losing 3 games to 1. Day 3: Symptoms continued, and for the first time he felt "seedy." After school he ran a half-mile race, and did not do as well as he expected. Day 4: The symptoms continued, but after lunch he developed a severe headache. He played tennis for half an hour, and that evening reported sick for the first time. He was put to bed, sleepless and restless. During the night severe paralysis developed in his trunk and lower limbs, and his arms also became weak. He kept moving his legs till they would move no longer, and developed retention of urine. On the ninth day his breathing became difficult and he was put in a respirator for three days. Four months later there was still gross paralysis of his trunk and thighs. The upper limbs were recovering well.

Therapeutic Applications

These case records make distressing reading in view of the evidence afforded by this study that physical activity is dangerous in the pre-paralytic stage. The danger of physical activity throws an extra responsibility on the practitioner regarding the need for early diagnosis. It is particularly important that he should be familiar with the possible ways in which the disease may present, so that strict rest can be enforced in all cases of doubt. Further, it is clear that restlessness in bed, pain, and resulting muscle spasm should be controlled, but I am not yet in a position to advise on the best drugs to use for this purpose. The need for complete rest in bed is very evident and the patient should lie quietly, moving or using his limbs as little as possible.

It should be emphasized that these records indicate not only that severe exercise in the pre-paralytic phase is highly dangerous, but that physical activity of any kind may be harmful. Tables II and III show that none of the patients

who stayed in bed after the onset of symptoms developed severe paralysis, and that all those who indulged in much physical activity for the two days following the first

1028 DEC. 27, 1947

## POLIOMYELITIS

meningeal symptom developed paralysis which was usually very severe. (Case 22 was excluded from these tables.)

## Summary

Forty-four patients convalescent from poliomyelitis, who were old enough to describe their symptoms, were questioned at length regarding their early symptoms and also the amount of physical activity during the early days of the disease.

The so-called meningeal symptoms appear in nearly all cases during the pre-paralytic stage of the disease and are of great value in diagnosis. These symptoms are often more suggestive of involvement of nerve roots than of meninges. They consist of pain in the head, neck, dorsal, lumbar, or sacral spine, scapular region, thighs, or the lower chest.

The meningeal symptoms may be slight or severe. At their onset the patient may be afebrile and may feel quite well. The meningeal symptoms may abate and the patient feel better shortly before paralysis develops.

Physical activity of any kind during the pre-paralytic stage increases the danger of severe paralysis. Complete physical rest in bed during the whole of the pre-paralytic stage seems to protect the patient from severe paralysis.

This study would never have been attempted but for the encouragement given by Dr. Allan McFarlan. I am particularly indebted to Dr. P. M. Daniel for helpful criticism, and to the following for access to cases under their care: Dr. H. C. Jennings, Oxford; Dr. W. H. Kelleher, London; Dr. A. Joe, Edinburgh; Dr. L. Guttman, Stoke Mandeville Hospital; and the Medical Superintendent of Monsall Hospital, Manchester.

NOTE—Case records giving the details required for this study will be welcomed for further analysis.

## POLIOMYELITIS AND POLIO-ENCEPHALITIS

### THE CASE FOR A REVIEW OF TERMINOLOGY

BY

L. H. MURRAY, O.B.E., M.D., D.P.H.  
 Medical Officer, Ministry of Health

From studies of clinical reports on cases notified as poliomyelitis and polio-encephalitis during the present epidemic it is evident that value can be obtained from a review of the varied manifestations of this disease, and an attempt made to correlate them into a reasonable clinical classification. As a result of this review certain recommendations are put forward.

**Illness of Infection.**—The existence of a true illness of infection is now accepted. This usually takes the form of mild fever and headache, with or without a nasopharyngitis, lasting one to two days, or of gastro-enteritis. Its onset probably occurs one to four days after the infection. Cases have been described in which the patients suffer from this initial illness but do not subsequently develop paralysis. Such cases are recognizable only among contacts of poliomyelitis during the course of an epidemic or unusual prevalence.

It is impossible, in the state of our present knowledge, to estimate the proportion of persons who have an illness of infection, but it may well be very large, and it is unknown as yet whether they assist in the spread of the disease as temporary carriers; such a possibility, however, must be entertained.

**Incubation Period of Recognizable Poliomyelitis.**—This is normally seven to 14 days, but there are outside limits of two days to 25 days, although it has been recorded that the virus was discovered in the stool of a person who developed clinical signs 19 days later. A few cases are on record of patients suffering vague signs and symptoms, persisting throughout the whole of the incubation period from the illness of infection—tingling in a muscle or muscle group, restlessness at night, listlessness, or vague signs of being off colour (Gartside, 1947).

**Proposed Classification.**—The subsequent progress of the disease may follow different courses. Clinically each case may be put into one of the following two categories: (1) non-paralytic poliomyelitis—(a) subclinical and (b) clinical; (2) paralytic poliomyelitis—(a) spinal, (b) bulbar, and (c) bulbo-spinal. In this classification—a clinical one—it will be noted that the term "abortive" has not been included in the types of disease. It is thought better to discontinue the use of this term, as "abortive" encourages a wrong concept of the subclinical cases (see below)—are abortive cases—like the subclinical cases (see below)—are particularly when it is appreciated that these two types form by far the greatest number of cases in an epidemic, have an equal if not more important role in the spread of the disease than the paralysed case, whose activities are necessarily restricted by virtue of the illness. Abortive cases should be termed "non-paralytic poliomyelitis," as there is no difference in the initial symptoms and signs of this type and those cases which go on to paralysis.

### Non-paralytic Poliomyelitis

#### Subclinical Poliomyelitis

In 1945 a team of workers in Chicago made a detailed study of 22 children after a known exposure to a case of poliomyelitis (Casey, 1946); 14 had a febrile illness between seven and 25 days after exposure. No comparable illness occurred in a group of 15 children, not so exposed, who lived near by. Among the 14 children who developed fever one had frank poliomyelitis; two had frank poliomyelitis without paralysis but with stiff neck, stiff back, head-drop, and increased cells and protein in the cerebrospinal fluid; four had fever and mild symptoms without stiffness in back or neck, or paralysis, but two of these gave a cerebrospinal fluid protein above 45 mg. The other seven children (the subclinical group) had axillary temperatures between 98.8° and 99.8° F. (37.1° and 37.7° C.), but seemed to have no symptoms; four of these, on lumbar puncture, gave protein figures of 45 mg. or more. Stool examinations revealed the presence of the virus just before or at the onset of the symptoms among most of the contacts with fever.

Though the figures are small, and further investigation is necessary, it does seem to indicate that poliomyelitis, during an increased incidence of the disease, is a mild, widespread, highly communicable disease particularly of young children, leaving no paralysis. It is impossible to state just how widespread is the dispersion of the virus, but it can with confidence be said that it is very considerable.

#### Clinical Poliomyelitis

It is felt that undue stress has been laid on the term "prodromal stage" or prodromal signs and symptoms, with the tendency to regard those cases which do not progress

beyond this stage as abortive cases, but the production of any prodromata is dependent on the virus having already gained entry to the body and on its producing its effect, so that, strictly speaking, there is no true prodromal illness, unless one regards the illness of infection as such.

In those cases in which symptoms referable to a prodromal period are present the virus has already gained a footing, but its action is slowed down, and instead of producing a clinical paralysis as a presenting sign it causes other effects referable to the central nervous system.

To indicate the march of the virus in the central nervous system after its invasion Faber (1933) describes the clinical features of the early stages of the disease as occurring in two phases.

**Phase 1.**—Drowsiness or restlessness and listlessness or irritability, mild fever, inversion of sleep rhythm, possibly vomiting, anorexia, and constipation. It is suggested that these symptoms are explicable by a subcortical origin in the thalamus or hypothalamus probably due to involvement of the brain stem or basal nuclei. Many cases do not progress any further than this stage, and recover rapidly and completely.

**Phase 2.**—Thalamic and hypothalamic symptoms persist, but the virus spreads to the posterior columns and root ganglia, producing sensory symptoms—neck stiffness, increased reflexes, muscular ataxia and tremors, muscle spasm, and spontaneous pains in muscles when the patient is touched or even approached.

In many cases the symptoms produced by phases 1 and 2 merge gradually one into the other, but often they are separated by a distinct interval with complete abatement of symptoms ("dromedary" cases). The severity of these early signs and symptoms bears no relation to the extent or degree of the ensuing paralysis or to the subsequent course of the disease.

The disease may halt at the end of these two phases and complete recovery take place. These are the true non-paralytic cases. If the early signs and symptoms were mild such cases were usually labelled "abortive"—i.e., abortive only in reference to the non-production of paralysis—but are nevertheless overt cases of infection by the virus.

Support for this concept of the disease, postulating some degree of general infection with a progressive invasion of the central nervous system, is given by Bodian (1947), who advances the theory, supported by neuropathological evidence, that every case of poliomyelitis has demonstrable pathological lesions in the brain.

The virus has been demonstrated in mesenteric and cervical lymph nodes and in the abdominal sympathetic plexus. Should further advances in laboratory technique simplify the demonstration of the virus it is a matter for speculation whether it will be discovered regularly in the blood and parenchymatous organs generally throughout the body. Such a possibility cannot be excluded on the existing evidence.

#### Lumbar Puncture

In this epidemic it has been the experience of many clinicians that changes have been discovered in the cerebrospinal fluid in the early stages of the disease—in some cases when the diagnosis was doubted and the clinical signs and symptoms of central nervous system involvement were minimal or absent. Fluids taken early tend to show a moderately increased cell count. Polymorphonuclear cells may amount to 90% of the total, but most specimens show lymphocytes and mononuclear cells almost exclusively. A slight rise in the protein content may or may not be found. The pressure is not often raised, but negative findings in the cerebrospinal fluid in the early stages do not necessarily exclude a diagnosis of poliomyelitis. Paralysis not infrequently develops later, after such a report has been obtained. The findings of Casey *et al.* (1946), described

under the heading of subclinical poliomyelitis, illustrate that changes are produced in the cerebrospinal fluid in a large number of persons who have been contacts of the disease in the presence of an epidemic or increased incidence of poliomyelitis.

Lumbar puncture is a valuable diagnostic aid in subclinical and non-paralytic cases, but should be carried out only after deciding that a degree of urgency to establish the diagnosis exists, because some clinicians believe that unnecessary manipulation of a poliomyelitis patient may increase the extent of the paralysis, should it occur, and lengthen convalescence.

#### Polio-encephalitis

From a study of the clinical reports on cases that have occurred in this epidemic it is obvious that many of those which have shown signs and symptoms of non-paralytic poliomyelitis—i.e., in one or both of the phases described by Faber—have been notified as polio-encephalitis. Other clinicians have based the diagnosis of polio-encephalitis solely on the production of cranial-nerve palsies—on the basis that the pathological lesion is within the skull. It is obvious that no single clear clinical picture of what constitutes polio-encephalitis is universally accepted.

In 1912, under the original Notification Order, it was not thought necessary to refer specially to acute polio-encephalitis—as the generic term "poliomyelitis" was comprehensive enough to cover all cases of the illness, including those in which cerebral symptoms predominated. In 1919, when cases of the then obscure encephalitis lethargica began to appear, it was decided to supplement the Regulations of 1912 and to require the separate notification of polio-encephalitis. This was to allow a differentiation between the incidence of the two diseases.

In 1919 the ratio of polio-encephalitis notifications to poliomyelitis was 1:10 (56:539). The comparative ratio for 1947 up to the end of October was 1:12 (587:7,438). This leads to the assumption that there has been neither any great variation in the number of cases exhibiting cerebral symptoms nor of the criteria adopted by practitioners in making the diagnosis polio-encephalitis; but confusion does exist, and must continue to exist so long as symptoms referable to one stage of a disease are singled out as a requirement for a separate notification. It is more paradoxical in the light of recent literature, which tends to show that in all cases of poliomyelitis pathological lesions can be demonstrated in the brain. It is therefore illogical to require the separate notification of polio-encephalitis.

#### Paralytic Poliomyelitis

As suggested above, cases which develop a lower motor neurone lesion may adequately be classified as (a) spinal type, (b) bulbar type, (c) bulbo-spinal type.

In the majority of cases in which paralysis occurs the virus exerts a selective action on the anterior horn cells of the lumbar and cervical enlargements of the spinal cord (the spinal type). In many cases signs of involvement of the cranial nerves appear either alone (bulbar type) or combined with peripheral nerve lesions (bulbo-spinal type). Because the bulbo-spinal cases form a large proportion of all clinical cases it is convenient to recognize them as a clinical group. These include all cases of paralysis in limbs, diaphragm, intercostals, abdominal muscles and neck and back muscles, and of the cranial nerves—all lower motor neurone lesions.

In 1885 Strümpell (quoted from Peabody *et al.*, 1912) described cases for which he used the term "polio-encephalitis." The onset was sudden, with fever, vomiting, and convulsions: after this the child (24 cases—all under

6 years of age, and 19 below the age of 4) developed a hemiplegia. Occasionally a monoplegia, or even an ataxia without paralysis, was noted. There was no atrophy or wasting of the muscles. Athetosis and disturbances of speech and intelligence were sometimes sequelae. Other similar cases of this type with spastic paralysis have occasionally been recorded in medical literature. These cases, presuming that they were true cases of poliomyelitis, could be accurately termed of cerebral type, with the site of the lesion in the motor cortex. It is possible that a true cerebral type exhibiting an upper motor neurone lesion will eventually be a recognized clinical type occurring in poliomyelitis, although Bodian (1946) produces evidence for the cerebral origin of spasticity in poliomyelitis in monkeys without lesions in the cord. It is wiser not to include this cerebral type until it is generally accepted that upper motor neurone lesions can be produced in monkeys and that the virus can be isolated from lesions producing these symptoms in man, and to restrict the clinical types of paralytic poliomyelitis for classification to bulbo-spinal, which category will include all cases producing signs of bulbar paralysis or of spinal paralysis alone, or both combined.

### Notification

Under existing regulations poliomyelitis is notifiable to the Registrar-General as poliomyelitis or polio-encephalitis. It would be an advance if the regulation making the separate notification of polio-encephalitis as distinct from poliomyelitis was superseded by one reverting once more to the generic term "poliomyelitis," which is to be used as a synonym for polio-encephalomyelitis. And if, in the future, poliomyelitis infections were to be classified as (a) poliomyelitis, non-paralytic, (b) poliomyelitis, paralytic, great assistance would be given to the medical officer of health and other epidemiologists in whose hands lies the responsibility for the control of epidemics in general and of preventing further cases of poliomyelitis in particular. The further division of non-paralytic cases into subclinical and clinical varieties has no place in an essentially administrative procedure like notification, but the information it would reveal would be invaluable in field investigations, were it easily available.

### Summary

The essential importance of the subclinical case and the mild non-paralytic case in the spread of the disease is demonstrated.

The concept that the diagnosis should take into account the signs and symptoms of involvement of the central nervous system other than paralysis is stressed.

The problem of the diagnosis of polio-encephalitis is discussed, and as a result a proposal is made to supersede the regulation requiring the notification of polio-encephalitis as a separate clinical entity and to revert to the single generic term "poliomyelitis" (syn. polio-encephalomyelitis).

The term "abortive" is discussed, and a suggestion is made that further differential notification is desired the classification should be non-paralytic and paralytic.

## DIFFERENTIAL DIAGNOSIS OF JAUNDICE BY FLOCCULATION TESTS

BY

J. BASIL RENNIE, M.D., M.R.C.P.

Senior Lecturer in Medicine in the University of Glasgow

With technical assistance of

S. L. RAE, A.I.M.L.T.

Senior Technician

(From the Gardiner Institute of Medicine,  
University of Glasgow, and the Western Infirmary)

The differentiation of jaundice due to obstruction of the larger ducts from that of hepatic origin is sometimes very difficult, particularly in patients over 40 years old. The van den Bergh test—a qualitative reaction—has proved of little value for this purpose, and many other tests of hepatic function have been tried singly and in combination. From the published reports of this work one or other of the flocculation tests would seem to be the best single diagnostic procedure, and they also have the advantage of being simple to carry out and requiring only small amounts of serum. Their chief disadvantage is that positive reactions occur in a small proportion of patients without evidence of hepatic disease.

These tests are more popular in the U.S.A., and although they have been used in this country, particularly by MacLagan (1944a, 1944b, 1947) and by Dick (1945) and Maizels (1946), it appears from comment in a leading article (*Lancet*, 1946) that their application is still not widely appreciated here. For that reason this report on the results obtained with the cephalin-cholesterol flocculation and serum-colloidal-gold tests has been drawn up.

The cephalin-cholesterol flocculation test was introduced by Hanger (1939) as an empirical procedure. Later work with electrophoresis showed that in parenchymatous disease of the liver there was an increase of the gamma fraction of the plasma globulin and a decrease of albumin. From the results of experiments *in vitro* Moore and his co-workers (1945) attributed flocculation of cephalin-cholesterol emulsion and also the precipitation of colloidal gold to these changes; Gray (1940) introduced the latter test. Positive results are reported commonly in hepatic and rarely in obstructive jaundice, and the tests are accordingly claimed to be useful in the differential diagnosis of these two conditions.

### Material and Technique

Our intentions in this investigation were to determine the value of two flocculation tests in jaundice, to establish that negative results were the rule in normal subjects, and to observe the results of the tests on patients without clinical evidence of hepatic disease. Accordingly observations were made on 110 patients with diseases of the liver, of whom 74 showed jaundice, on 100 controls drawn from donors of blood, and on 281 patients who suffered from a variety of conditions but showed no clinical evidence of hepatic disease. Both tests were carried out on the same sample of serum from each of the 491 subjects tested.

**Cephalin-Cholesterol Flocculation Test.**—The method and the technique for the preparation of the emulsion were those of Hanger (1939). The cephalin was used immediately, without a period of storage, to make the stock emulsion. This showed no change in sensitivity when kept as long as three months in a refrigerator, as Dick (1945) has recorded. The test was read at 24 hours.

**Colloidal-Gold Reaction.**—The method was that of MacLagan (1944a). The gold sol was made according to the method of Mellanby and Anwyl-Davies (1923).

**Interpretation.**—The results of both tests are customarily given as 0, 1+, 2+, and so on up to complete flocculation or precipitation, which is 4+ with the cephalin and 5+ with the gold test. It has always seemed to us difficult, if not impossible, to differentiate, for example, 2+ from 3+, and in this series only 3 gradings have been used: no flocculation (or precipitation), flocculation present, and flocculation complete.

### Results of Tests

(1) **Normal controls.**—For this group blood donors were used ranging in age from 16 to 60. All seemed well except eight who suffered from hypertension. The plasma bilirubin was within normal limits in all. In the 100 normal controls no flocculation was found with either test.

(2) **Patients without Clinical Evidence of Hepatic Disease.**—Positive results with both tests have been recorded in patients of this category. With the cephalin test the proportion of such have ranged from 3% (Pohle and Stewart, 1941) to 18% (Wade, 1946). Later reports have indicated that, in particular, positive flocculation tests are common in rheumatoid arthritis (Carter and MacLagan, 1946), thyrotoxicosis (Pohle and Stewart, 1941), severe anaemia (MacLagan, 1944a), virus diseases and other infections (Gray, 1940; Pohle and Stewart, 1941; MacLagan, 1944a), and heart failure (Gray, 1940; Carter and MacLagan, 1946).

The results of observations with both tests on 281 patients are shown in Table I. Negative reactions were found with cephalin emulsion in 91.8% and with gold in

TABLE I.—Results of Cephalin and Gold Tests on 281 Patients without Clinical Evidence of Hepatic Disease

Group	No. of Cases	Negative		Positive		Complete Precipitation	
		Ceph- alin	Gold	Ceph- alin	Gold	Ceph- alin	Gold
C.N.S. ..	32	32	32	0	0	0	0

Percentage excluding rheumatoid arthritis	..	92.2	90.4	6.6	6.3	1.1	2.9

87.9%. Complete precipitation of gold occurred in 4.2%, but complete flocculation of cephalin in only 1.1%. Analysis of the groups into which the cases were divided gave the following results. In patients with disease of the nervous system and with nephritis neither test was ever found to be positive. Nephritis of all types and in all stages was investigated, but the finding of Maizels (1946) that the cephalin test is sometimes positive was not confirmed. Positive tests occurred in 4 out of 32 patients with peptic ulcer, 2 of whom had had recent bleeding. The occurrence of positive reactions in the group of patients with infections was inconstant and appeared to bear no relation to the nature or severity of the infection or to the presence or absence of fever. For example, 1 patient with subacute bacterial endocarditis showed maximum-positive reactions to both tests, but 3 others, equally ill, gave negative results. Similar inconsistencies were also seen in the heterogeneous group labelled sundry. Two out of 11 patients with diabetes and 3 out of 8 with thyrotoxicosis gave positive reactions; this may have been evidence of a special tendency, but the numbers are too small to be certain. In rheumatoid arthritis, however,

the incidence of positive gold reactions was undoubtedly high—8 out of 11 patients. If this group is omitted from consideration, the incidence of positive reactions with the cephalin and gold tests in patients without clinical evidence of hepatic disease becomes almost the same (Table I), the incidence of positive reactions being less than 10%.

(3) **Hepatic Disease with Jaundice.**—The results of observations on 74 jaundiced patients are shown in Table II. The clinical diagnosis of the cause of the

TABLE II.—Results of Cephalin and Gold Tests on 74 Patients with Jaundice

	No. of Cases	Negative		Positive		Complete Precipitation	
		Ceph- alin	Gold	Ceph- alin	Gold	Ceph- alin	Gold
Obstructive jaundice: Tumour or calculus	32	27	27	4	5	1	0
Percentage ..	..	84.4	84.4	12.5	15.6	3.1	—
Hepatic jaundice: Cirrhosis and subacute necrosis	18	0	2	2	2	16	14
Banti's syndrome ..	4	2	1	1	2	1	1
Acute infective hepatitis	17	5	2	6	5	6	10
Homologous serum jaundice	3	3	3	0	0	0	0
Total hepatic jaundice	42	10	8	9	9	23	25
Percentage ..	..	23.8	19.0	21.4	21.4	54.8	59.5

jaundice was substantiated by operation, post-mortem examination, and in a few instances by puncture biopsy, or was considered reasonably certain from the course of the disease—as, for example, in most instances of acute hepatitis.

In the 32 patients of the obstructive group positive reactions occurred in less than 16% of both tests. Complete precipitation was noted once with cephalin and not at all with gold. In contrast, the group of 42 patients with hepatic jaundice showed positive results in 76% of cephalin and 81% of gold tests. In more than half precipitation was complete. Analysis of the subgroups of hepatic jaundice shows that a positive gold test was present in all patients with cirrhosis or subacute necrosis of the liver. The cephalin test was positive in all but one, and with both tests precipitation tended to be complete. Both tests were negative in three patients with homologous serum jaundice.

In Table III are shown the findings with the two tests in patients with disease of the liver but without jaundice.

TABLE III.—Results of Cephalin and Gold Tests on 35 Patients with Hepatic Disease without Jaundice

	No. of Cases	Negative		Positive		Complete Precipitation	
		Ceph- alin	Gold	Ceph- alin	Gold	Ceph- alin	Gold
Metastatic carcinoma	8	5	7	0	1	0	0
Cirrhosis, including Banti's syndrome	4	2	0	3	2	3	6
Reticuloses ..	4	2	2	2	0	0	2
Haemochromatosis	2	2	2	0	0	0	0
Chronic leukaemia ..	3	3	0	0	0	1	1
Cardiac failure with hepatic enlargement	11	8	7	2	3	0	0

Negative tests were found in all but one case of metastatic carcinoma of the liver. Positive results were found in cirrhosis and in Banti's syndrome. In a small group of 9 patients with reticuloses, haemochromatosis, and chronic leukaemia both tests were found to be positive on three occasions. Of 11 patients with cardiac failure and hepatic

enlargement flocculation tests were positive in 3. Carter and MacLagan (1946) observed positive gold tests in 11 out of 28 cases and found no relation between the size of the liver and the incidence of positive reactions in cardiac failure.

### Discussion

In a series of patients of both sexes without clinical evidence of hepatic disease the incidence of positive reactions was under 10% with both tests if rheumatoid arthritis was excluded. Although the mechanism of both tests is apparently due to the same changes in the plasma protein (Moore *et al.*, 1945), it was noticeable that the reactions were not always parallel in the same plasma, and indeed a negative result with one test sometimes accompanied a positive with the other. The number of patients suffering from conditions other than hepatic diseases (in which other workers have reported a high incidence of positive results) was rather small, and in only two groups could these findings be confirmed. The 8 positive gold reactions in rheumatoid arthritis could be accepted as significant even in a group of only 11 patients. The next highest incidence of positive reactions was in the group of 61 infections, in which 16.4% of cephalin tests and 19.6% of gold tests were positive.

In 200 patients without jaundice MacLagan (1944a) found 31, or 15.5%, who showed positive gold tests. He considered that virus infections, or constitutional disturbance with fever or cachexia, were associated with all of these positive reactions, which did not, however, invariably accompany these conditions.

### Differential Diagnosis of Jaundice

In jaundice due to obstruction of the larger ducts by tumour or gallstones negative results were the rule. Positive reactions were obtained in 5 out of 32 patients, and in 3 of these jaundice had been present for more than four weeks. On the other hand negative results were found in several patients who had had complete biliary obstruction for over two months, a finding which did not support the view that positive tests are found only when the hepatic cells are damaged by obstructive jaundice of long duration. The practical point is that the flocculation tests tend to be negative in obstructive jaundice whatever its duration. In contradistinction a high proportion of patients with hepatic jaundice gave positive results. Difficulty in differential diagnosis of hepatic from obstructive jaundice may arise, particularly in patients suffering from subacute necrosis of the liver and acute infective hepatitis. In the former, both tests were invariably strongly positive (7 cases). In the latter, positive results, particularly with the gold test, were usual, but exceptions were occasionally noted.

Maizels (1946) states that jaundice accompanied by negative flocculation tests should improve within two weeks if it is due to hepatitis. In this connexion it may be observed that mild attacks were not necessarily accompanied by negative tests, since complete precipitation was observed in 2 patients whose plasma bilirubin never rose above 3.0 mg. per 100 ml. Of the two patients who gave negative results, one was not tested until convalescent and the other was a mild case who improved rapidly. Hanger and Gutman (1940) recorded negative cephalin tests in arsenical jaundice, and Turner *et al.* (1944) in a small proportion of patients with hepatitis due to yellow-fever vaccine. In the latter, hepatic-function tests remained unimpaired and the results resembled those found in obstructive jaundice. Three patients with homologous-serum jaundice in this series gave negative results to both tests. From these findings flocculation tests are of no value in

diagnosis so far as homologous-serum jaundice is concerned, but in that group the history provides a useful indication.

In cirrhosis, jaundice is not usually a prominent feature, and difficulty in differential diagnosis is less likely to arise. Positive tests were the rule.

As regards the relative incidence of positive results with the two tests, of 110 patients with hepatic lesions cephalin flocculation was observed in 48 and gold precipitation in 54. Of 270 patients without clinical evidence of hepatic disease, rheumatoid arthritis being excluded, the cephalin test was positive in 21 and the gold in 26. If rheumatoid arthritis, in which a high proportion of gold tests are positive, was excluded, the results were much the same with both tests and particularly in the group with jaundice. Since the gold test is carried out with standard solutions of known chemical constitution it would appear to be the procedure of choice.

### Summary

Observations were made with the cephalin-cholesterol flocculation and serum-colloidal-gold tests on 491 subjects comprising 100 normal controls, 110 patients with hepatic disorders, and 281 patients without clinical evidence of liver disease.

In 100 controls both tests were negative.

Of 270 patients without clinical evidence of hepatic disease the cephalin test was positive in 7.8% and the gold test in 9.6%. Positive results with both tests were found in all conditions in this group except diseases of the central nervous system and nephritis, but appeared to be most frequent (excluding rheumatoid arthritis) in patients with acute infections. No constant factor could be found in these or other members of the group to account for the positive flocculation tests. Rheumatoid arthritis was associated with 8 positive gold reactions in 11 patients.

Of 32 patients with obstructive jaundice both tests were positive in 15.6%; complete precipitation was infrequent. In contrast 76.2% of cephalin and 81% of gold tests were positive in jaundice of hepatic origin, and complete precipitation was noted in more than half the cases.

In persistent jaundice due to cirrhosis or subacute necrosis positive reactions were the rule and were helpful in differentiating the condition from obstructive jaundice.

The gold test would appear to be the more satisfactory of the two procedures since it is carried out with standard solutions of known chemical constitution.

The Essex Hospitals Joint Advisory Council was formed following conferences called by the Nuffield Provincial Hospitals Trust. The primary purpose of the Council was the discussion, so far as it related to the County of Essex, of the factual parts of the 1945 Report of the Surveyors of the Hospital Services of London and the Surrounding Area. The Council set up a subcommittee to consider and advise on the problems raised by the Survey, and the report of this subcommittee is now available and can be obtained from the Nuffield Provincial Hospitals Trust, 12 and 13, Mecklenburgh Square, London, W.C.1.

## PARACOLON BACILLUS INFECTION CAUSING CHOLECYSTITIS AND SUPPURATIVE HEPATITIS

BY

KENNETH WALTON, M.B., B.S.

Late Major, R.A.M.C.; Specialist in Pathology

AND

J. C. LEEDHAM-GREEN, F.R.C.S.

Late Lieutenant-Colonel, R.A.M.C.; Officer in Charge of  
Surgical Division

In the following case, which occurred after an attack of dysentery, the somewhat rare sequels of acute cholecystitis and suppurative hepatitis developed, and a paracolon bacillus was recovered from the blood stream and from the gall-bladder during the infection and from the lesions in the liver at necropsy. This organism did not seem to be identical with *Bact. asiaticum*, but appeared to produce an infection of an equal if not a greater degree of virulence.

### Case History

An officer aged 36 was admitted to a British general hospital in Calcutta on June 7, 1945, complaining of acute pain in the right hypochondrium, which had come on suddenly ten hours previously. He had vomited several times. There was no history of dyspepsia or biliary colic. He had served in India for thirteen months, and his only other illness had been an attack of "clinical dysentery" eight weeks previously.

On admission he was in obvious pain and very distressed. The temperature was 101.4° F. (38.55° C.), pulse 102, and respirations 20. There was tenderness in the right hypochondrium, with guarding of the muscles of the right upper quadrant but no rigidity. The urine contained no albumin or sugar, but there was a deposit of phosphates. No other abnormal physical signs were elicited. A diagnosis of acute cholecystitis was made. The following day he was still in pain and lay curled up on his right side. By the next day rigidity of the muscles of the upper right abdomen had developed.

**Operation** (Lieut.-Col. Leedham-Green).—The liver was normal but the gall-bladder was seen to be plum-coloured and distended. Aspiration of the gall-bladder yielded pus. The common bile duct was normal in colour and not dilated. Cholecystectomy was performed and the abdomen closed with drainage. The common bile duct was not explored. On opening the removed gall-bladder viscid pea-green fluid was found but no mud or stones. The mucosa was not grossly ulcerated.

**Histological Report.**—Microscopically, section showed ulceration of the mucosa and infiltration of the whole thickness of the wall of the gall-bladder with inflammatory cells. The capillaries were distended and hyperaemic. The submucosa and muscular layers were oedematous and packed with polymorphonuclear leucocytes. Pus from the gall-bladder yielded an atypical (anaerogenic) paracolon bacillus in pure culture.

**Post-operative Course.**—On the day after operation it was disturbing to find the patient drowsy and still complaining of the pain in his right side, which was as severe as before the operation in spite of the removal of an obviously diseased gall-bladder. This pain diminished gradually during the days that followed, but it was difficult to assess its intensity accurately since his drowsiness was succeeded by increasing restlessness with intervals of delirium. For the first few days after operation his temperature remained around 101° F. (38.3° C.) and subsequently swung between 97° and 100° F. (36.1° and 37.8° C.). Blood culture on June 14 yielded an anaerogenic paracolon bacillus which appeared to be identical with the organism from the gall-bladder. A blood count on June 18 showed: R.B.C., 3,430,000; W.B.C., 6,800 (polymorphs 76%; lymphocytes 24%). A course of sulphamezathine (total 54 g.) produced no clinical improvement, although a second blood culture on June 20 was negative. By June 27 he had become jaundiced and bedsores had developed over the sacrum. Increased

tenderness over the lower border of the liver was again noticed. He died on July 11, 32 days after operation.

**Post-mortem Report.**—The liver was enlarged (weight 8½ lb. —3.74 kg.) and of a mottled grey-green colour. The cut surface showed small haemorrhagic areas alternating with pale areas in an irregular pattern. Scattered throughout the liver substance were friable necrotic areas containing yellowish-green material which appeared to be a mixture of pus and bile. The hepatic and common bile ducts contained thick, viscid green bile. The mucosa of the ducts was deeply stained with bile and appeared to be chronically inflamed. There was no obstruction to the flow of bile, which was found staining the food residue in the stomach. The spleen was enlarged and friable. The kidneys were congested. Evidence of embolic spread to other sites was not seen and no significant changes were found in the other organs. Microscopical examination of the liver revealed multiple pyogenic abscesses scattered throughout its substance. Parenchymatous cells had survived in small areas, but those on the periphery of the abscesses showed an advanced degree of fatty degeneration. The bile ducts near the abscesses were filled with bile and polymorphonuclear leucocytes. In those areas where normal liver tissue survived, the portal and central hepatic veins showed no pathological change. Section of the spleen and kidney revealed no evidence of embolic spread of infection.

**Bacteriology.**—The organisms recovered from the aspirated contents of the gall-bladder and from the blood had identical characters. Each was a Gram-negative motile rod and formed a pellicle on incubation in broth. Each gave identical biochemical reactions as follows:

Lactose ..	A	Maltose ..	A	M.R. ..	—
(slow: 48 hrs.)		Saccharose ..	A	V.P. ..	—
Glucose ..	A	Dulcitol ..	—	Citrate ..	—
Mannitol ..	A	Indole ..	+		

A = production of acid. No gas was produced in any carbohydrate on incubation up to 21 days.

**Serological Reactions.**—Neither organism was agglutinated by the stock *Salmonella* sera (including a non-specific *Salmonella* serum containing the common antigenic components of the group) nor by the stock dysentery-group sera. Against the patient's own serum agglutination occurred as follows:

Serum	June 22		June 29		July 10	
	Patient	Control	Patient	Control	Patient	Control
Organism B ..	1/500	Nil	1/1000	Nil	1/2500	Nil
Organism G ..	1/500	Nil	1/1000	Nil	1/2500	Nil

Organism B isolated from blood culture, organism G from gall-bladder.

An organism isolated at necropsy from one of the abscesses in the liver had identical biochemical reactions and was agglutinated by the patient's serum to a titre of 1/500. Facilities for the antigenic analysis of these organisms were not available.

Judged by its biochemical reactions the organism appeared to belong to the paracolon group. Numerous workers who have studied the paracolons (Dudgeon and Pulvertaft, 1927; Fothergill, 1929; Jones, Orcutt, and Little, 1932; Kennedy, Cummings, and Morrow, 1932; Sevitt, 1945) have experienced difficulty in classifying them. In our case the organism seemed to be related to Group B of Dudgeon and Pulvertaft's classification or to Group IV in that of Sevitt. According to Sevitt, organisms of Group IV are antigenically heterologous and not antigenically related to the Flexner bacilli nor to *Bact. alkalescens* as are certain other strains of paracolon bacilli.

We record our thanks to Professor Sir Lionel Whitby for his comments on the bacteriology of this case, and to Colonel W. Bruce, late R.A.M.C., officer commanding B.G.H., and the Director-General, Army Medical Services, for permission to publish.

## Medical Memoranda

### Uveoparotid Syndrome (Heerfordt's Disease)

The syndrome of uveitis-parotitis-polyneuritis, or Heerfordt's disease, is now well recognized as one of the manifestations of sarcoidosis or lymphogranulomatosis benigna. A number of cases of the syndrome have been described in which attention is drawn to the changes in the cerebrospinal fluid, but examination of these cases suggests that such changes, if present, are slight and of no diagnostic importance. Attention is here drawn to a case of Heerfordt's disease, with gross changes in the cerebrospinal fluid demanding major consideration in diagnosis. Moreover, the changes found, despite the very mildest indications of polyneuritis, strongly suggested a polyneuritis of the toxic-infective kind.

#### CASE REPORT

An upholsterer aged 17 was admitted to hospital on June 25, 1946, complaining of malaise, anorexia, frontal headache, and mistiness of vision for five days. His medical and family histories revealed nothing of note. Examination showed a well-developed youth, somewhat flushed, with a pyrexia of 100° F. (37.8° C.), the only finding on admission being a mild bilateral iridocyclitis. Both conjunctivae were markedly injected, the corneas hazy, and the pupils irregular, with a sluggish light response. No synechiae or keratic precipitates were found. The remainder of his central nervous system, including his fundi, was normal.

On June 28 he was found to have a right facial palsy of the lower motor neurone type, and it was noted that the knee-jerks, which had previously been present, were now absent. His temperature had settled, the eye condition remained unchanged, but his headache was less severe. On July 1 a slight but definite swelling, tender to palpation, affecting the pre-auricular portion of the right parotid gland was noted. Examination of his central nervous system on this date showed bilateral facial paralysis of lower motor neurone type and complete absence of all deep reflexes in both arms and legs. There was no weakness or wasting of the limb or trunk musculature. Abdominal reflexes were brisk and the plantar responses flexor. There was no loss of superficial or deep sensation.

A blood count gave the following result: R.B.C., 5,200,000 per c.mm.; Hb, 106%; colour index, 1; white cells, 13,000 per c.mm. (polymorphs, 83%; eosinophils, 1%; lymphocytes, 12%; monocytes, 4%). The cerebrospinal fluid on July 1 was clear and under normal tension—cytology: W.B.C., 68 per c.mm. (lymphocytes, 96%; polymorphs, 4%), R.B.C., 7 per c.mm.; total protein, 220 mg. per 100 ml.; globulin, a heavy excess; glucose, 74 mg. per 100 ml.; chlorides, 620 mg. per 100 ml.; films, no tubercle or other organisms seen; culture, sterile; W.R., negative; Lange, 1111211000.

On July 3 a tender swelling was noted in the left parotid region, similar to that on the right side. The blood W.R. and Kahn test were negative and x-ray examination of the chest revealed nothing abnormal. On July 8 the cerebrospinal fluid showed W.B.C., 60 per c.mm. (lymphocytes, 98%; polymorphs, 2%); total protein, 120 mg. per 100 ml.; globulin, a fair excess; glucose, 78 mg. per 100 ml.; chlorides, 650 mg. per 100 ml.; Lange, 1112344321; films, no tubercle or other organisms seen. The cerebrospinal fluid on July 17 showed W.B.C., no excess; total protein, 90 mg. per 100 ml.; globulin, a fair excess; glucose, 54 mg. per 100 ml.; chlorides, 700 mg. per 100 ml.; Lange, 0001111000.

The patient's condition remained unchanged for about a week, and then gradually began to improve. The swelling of his face disappeared, and the deep reflexes returned. The bilateral facial paralysis likewise slowly improved, the left side more rapidly than the right. He was finally discharged home, completely recovered, on Aug. 23.

#### COMMENT

Since the original description by Heerfordt in 1909, many cases of uveoparotitis have been described, but in few have changes in the cerebrospinal fluid been found. In the cases described by Feiling and Viner (1921) and Macbride (1923) the only abnormality detected in the cerebrospinal fluid was a slight increase of lymphocytes—15 and 18 per c.mm., respectively. On the other hand, Middleton (1946) stated that pleocytosis and increased proteins in the cerebrospinal fluid may occur in the uveoparotid syndrome, but gives no reference to any specific case or cases.

There can be little doubt that the above case was one of Heerfordt's disease. The occurrence of bilateral facial palsy and the loss of tendon reflexes together with the cerebrospinal fluid changes would have led to a diagnosis of infective polyneuritis, but the association of these findings with uveitis and

parotitis, and the absence of motor weakness and sensory changes, complete the diagnosis of Heerfordt's disease. The possibility of mumps with complicating polyneuritis and iridocyclitis is excluded by the onset of iridocyclitis and facial paralysis before the development of parotid swellings.

I wish to thank Dr. Blake-Pritchard, consulting neurologist, and Dr. W. G. Sears, medical superintendent, for their kind assistance with this case, and Dr. A. B. Rosher for the laboratory investigations.

### Ulceration of Wedding-ring into Phalanx

Below is presented a clinical curiosity which may well be unique, for I have been unable to find any reference to a similar case.

#### CASE HISTORY

The subject was a lady, aged 73, who was being treated for hypertensive heart failure, diabetes mellitus, and iron-deficiency anaemia. It was noticed that under almost all circumstances she kept her left hand hidden beneath the bedclothes. She was persuaded with some difficulty to uncover it, and after some adhesive strapping had been removed the following interesting condition was disclosed. Two-fifths of the circumference of her wedding-ring of 22-ct. gold lay within a tunnel passing through the proximal phalanx of the left ring-finger (Fig. 1). The remaining three-fifths lay outside the finger. The ring could be freely rotated through the tunnel.

FIG. 1

FIG. 2

The latter was not epithelialized, yet there was no sepsis or discharge. Skiagrams showed erosion of the greater part of the thickness of the proximal phalanx and bony ankylosis of the proximal interphalangeal joint. Dr. Pezeshgi kindly removed the ring, after which the tunnel and its two orifices soon healed. A skiagram of the finger 15 months later showed only a very slight filling in of the bony defect (Fig. 2).

#### COMMENT

The means whereby the ring came to lie in this curious position were as follows. Originally there had been an engagement ring placed distally to the wedding-ring, and, being of lower carat and therefore harder than the wedding-ring, it had by constant friction worn a sharp-edged bevel on the distal rim of the latter. Some fifteen years ago this sharp edge had abraded the skin, and repeated trauma had induced a progressively deepening ulceration. The ring sank slowly deeper, until six years later a bridge of soft tissue covered by skin grew over the now sunken portion. Penetration continued until the present state was reached and the deep portion was more than half-way across the thickness of the finger.

Dulwich Hospital, S.E.22.

## Reviews

### OBSTETRICS AND GYNAECOLOGY

*The Essentials of Obstetrics and Gynecology.* By William Albert Scott, M.B., F.R.C.S.(Can.), F.R.C.O.G., and H. Brookfield Van Wyck, M.B., F.R.C.S.(Can.), F.R.C.O.G. (Pp. 390; 91 illustrations (13 in colour). 27s. 6d.) London: Henry Kimpton. 1947.

The authors of this new textbook from the Toronto school attempt to set out briefly the fundamentals of obstetrics and gynaecology, bearing in mind the composition of the basic course of lectures given to undergraduates in the university. They considered that an outline of the subject that afforded a simple exposition without including controversial matter might be useful to undergraduates, who tend to flounder when they start a new subject unless guided systematically through the mass of detail accumulated in more exhaustive treatises. The authors have succeeded admirably in their task, and the student may learn from this book the essentials of the two subjects without having his mind burdened with details of treatment (which in any case are constantly changing) that can be found, if required, in books of reference.

While the whole book is good, some sections are outstanding, notably those on the physiology of pregnancy and on hyperemesis gravidarum. It is regrettable that in discussing placenta praevia the authors do not mention expectant treatment unless the patient is in labour. They state that the object of treatment is "the termination of the pregnancy in a manner that will control blood loss during the process and yet carry the least danger to the mother." Surely another object is to secure the survival of the child—in so far as that does not conflict with the safety of the mother. If expectant treatment is never used, prematurity will be unduly common and the sacrifice of child life unnecessarily great. We are unable to agree with some of the statements made in the chapter on toxæmia, such as "the first warning [of the onset of pre-eclamptic toxæmia] is usually some degree of albuminuria"; and "it must be remembered that the longer the toxæmia lasts the greater the probability of permanent renal damage." The description (at p. 101) of Credé's method of expressing the placenta is inaccurate and might be dangerously misleading to a beginner. On p. 172 the authors promise to describe the operation of breech extraction in the chapter on operative obstetrics, but we cannot find any reference to it there or elsewhere.

The authors cover gynaecology in 150 pages, yet omit little of importance, and find space for separate short chapters on sterility, contraception, and diseases of the intestinal tract in relation to gynaecology. The chapter on ovarian tumours is particularly good, and little of importance is omitted from its 20 pages. The illustrations are particularly clear (and are original) with the exception of that of the Krukenberg tumour, which fails to show the tumour's characteristic feature—that is, the signet ring cells.

We strongly recommend the book to the student and practitioner. The latter, though he will have to refer to larger books for many details of treatment, will yet find much of value in it, as the reviewer has done.

F. J. BROWNE.

### A NATIONAL PROBLEM

*Unwanted Child.* By Dr. Eustace Chesser. (Pp. 169. 12s. 6d.) London: Rich and Cowan.

The purpose of this book is to draw attention to the tragedy of the unwanted child—and a grim picture it is, as the case histories reveal. The author suggests measures of prevention (which he admits are not new) in a clear, forceful, and readable style. He does not discuss how to deal with the unwanted child himself once the deprivation of love and security has had its almost inevitable effect, perhaps because by then the degree of mental disorder is so great that little can be done unless it is possible to remould entirely the outlook and character of the unfortunate victim. Prison cannot effect such a change, and the most painstaking psychotherapist, who can treat only the very few, experiences great difficulty.

Dr. Chesser has many interesting things to say on this most troublesome social problem. For example, he insists that parents should recognize their own share of blame in the processes by which their children have gone wrong, especially if these children have been unwanted. The faults of the parents are chiefly due to selfishness and ignorance, and unless the ignorance can be dispelled in one generation it is likely to recur in the next. He draws attention to the variety of circumstances which lead parents to resent the birth of children. Discussing the anomalies of the law of alimony for unmarried mothers, he points out how relatively seldom the meagre allowance (20s. a week maximum) is sought. Obviously some reconsideration of the law is required so that it may satisfy the real need of the unfortunate without being open to abuse by the vindictive woman. He pleads that our new education, when it really fulfils its function, should include social education and the training of the emotional life as well as factual instruction, and he mentions the evils of sex ignorance and the need for a guide to more rational sex education. There is an interesting but certainly controversial chapter in which the author suggests extending permission for "legal" abortion in the interests of the mother's health, mental as well as physical, and draws attention to the position of the child who might indeed be better never to have been born. There are a useful bibliography, a list of societies interested in such social problems, and recent statistics of births, infantile mortality, and affiliation orders.

R. G. GORDON.

### FIELD HYGIENE

*Handbook of Preventive Medicine.* Air Publication 1269b. (Pp. 213; illustrated. 7s. 6d.) London: H.M. Stationery Office. 1947.

This R.A.F. *Handbook of Preventive Medicine* is better than any previously issued Service manual on the subject. The material has not been substantially changed in this edition, but for the first time the reader does not have the uncomfortable feeling that the writers saw service in the South African War.

There are full accounts of the basic methods for keeping troops in the field healthy, disposing of waste material, supplying clean water, field-cooking, disinfesting, etc., and the sections incorporate the advances in knowledge made possible by recent research and war experience. The chapter on the physical environment is very full, and the section on thermal environment, where the physiology of heat and fluid loss are also considered, is particularly good. It is disappointing to find so little said on industrial hazards, nothing systematic on mental hygiene, and only a few sketchy remarks on food inspection. It is surprising to read in the section on infectious disease that all malaria cases should be nursed under nets. No problems specific to aviation medicine are discussed. It is difficult to see why there should not be a joint Services manual on this subject, for the problems and the approach to it are essentially the same.

J. M. MACKINTOSH.

### MONOGRAPH ON SILICOSIS

*La Silicosis Pulmonar.* By Dr. Hugo Dooner. (Pp. 195; illustrated. No price given.) Santiago de Chile: Empresa Editora Zig-Zag, S.A.

Chile being a country where there are many miners, Dr. Hugo Dooner has not found it difficult to collect material for his monograph on pulmonary silicosis. He says that he has studied the problem in South Africa as well as in the mines of Potrerillos in his own country. Beginning with a brief historical outline, in which he attributes the first clinical description to Hippocrates, who named the condition "miner's phthisis," Dr. Dooner passes on to define the modern conception of the pneumoconioses and to determine the aetiological importance of silica. He then discusses the significance of free silica, the density and size of the silica particles in the atmosphere to which the worker is exposed, the quantity of silica present in the terrain being mined, and the length of exposure. He also considers, under predisposing factors, other infections in the respiratory tract—for example, sinusitis, chronic bronchitis; the constitution of the worker

(those of a "lymphatic" constitution having a greater predisposition); and the type of work undertaken in the mines. Then follows a section on the pathology of the condition, which is marred by the few and indifferently reproduced photomicrographs, the degree of whose magnification is not given.

In a monograph such as this we had hoped for a discourse on the pathological features (and especially the complications) rather than a statement of facts already well known. Dr. Dooner rightly emphasizes that the diagnosis of silicosis depends little on symptoms and signs: a history of exposure and expert radiological interpretation are all-important. This being so, it is unfortunate that the fourteen skiagrams included are so poorly reproduced that even such a gross lesion as a large cavity (for example, that marked by arrows in Fig. 15, p. 123) requires the eye of faith to distinguish it. Moreover, the author intends many of these skiagrams to illustrate the numerous existing elaborate classifications of silicosis—North American, South African, English, German, and South American—and this aim is hardly achieved. It seems a pity that more has not been made out of such material.

A. MORTON GILL.

### RIPE RECOLLECTION

*The Occasion Fleeting.* By Hugh Barber. (Pp. 200. 15s.) London: H. K. Lewis and Co. 1947.

Dr. Hugh Barber has written the best sort of autobiography. In these essays he has drawn an attractive self-portrait, setting himself solidly between covers so that the reader may share his experience, his pleasures, his ideas, and his prejudices. Their chief merit lies in the author's shrewd observation of men and women, in his devotion to his profession and his care for its traditions. The publication of these essays just now has a particular importance because physicians of the author's generation not only forged the link between the art and science of medicine, but they have carried the ideals of English medicine from the death of the old system to the birth of the new. There is much here to inspire and encourage the young medical practitioner—particularly the family doctor—as he emerges into his new status, and also not a little to warn him. For the author says to him in effect, "You are packing for your journey; well, I should take this with you; and this, too, it would be a misfortune to discard; that looks old-fashioned and a bit threadbare, but like the gold-headed cane it has a tradition behind it."

These essays are witty, allusive, colloquial in style, and they are crowded with quotation and anecdote. They are garnished with delightful fables, of which the following short example must serve:

"'Some people,' said the Healthy Man, 'recommend a routine medical examination once or twice a year.'

'Yes,' said the Doctor.

'You, yourself,' said the Healthy Man, 'could have such an examination without expense and with little inconvenience.'

'Yes,' said the Doctor.

'When were you examined?' asked the Healthy Man.

'I hardly remember,' said the Doctor. 'Once, I think, as a medical student, once for life insurance before I got married, and again in the 1914 war for military service.'

'I see,' said the Healthy Man. 'Thank you.'

Of the author's writing it may be said that he has studied the best masters, but he does not seek to imitate them. If one may borrow a metaphor from his beloved game of cricket, although his bat has a short uplift he knows where to put his left foot and his left elbow; he knows too what he can do and, Yorkshire-like, is neither frightened by this knowledge nor deterred by the spectators; while, most important and most characteristic of all, he is never tempted to wild indiscretions half-way down the pitch. Altogether this is a book which any senior physician would be glad to have written and which any young physician would do well to read.

D. V. HUBBLE.

*Éléments de Physiologie Humaine* (Paris: Librairie Maloine. Paper 150 fr.; bound 350 fr.) is one of a series written by Prof. L. Launois and intended for students at the Faculté de Pharmacie of Paris. He seems to stress the chemical aspect, but it is up to date and well written despite its sometimes having the appearance of a compilation. There are relatively few figures—probably because the book is intended as a companion to a course of lectures.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Internal Medicine in General Practice.* By R. P. McCombs, B.S., M.D., F.A.C.P. 2nd ed. (Pp. 741. 42s.) Philadelphia and London: W. B. Saunders Company. 1947.

An account of the medical problems most commonly met with in general practice.

*XII Conferencia Sanitaria Panamericana.* Nos. 3-10, 12, 15, 17, 20-30. Caracas: Editorial Grafolit. 1946.

Papers read at the conference.

*Science News V.* Edited by John Enogat. (Pp. 165. 1s.) Penguin Books. 1947.

Essays in popular science on such topics as microscopes, meteors, speleology, and rain.

*Synopsis of Obstetrics.* By J. C. Lützenberg, B.Sc., M.D.; F.A.C.S. 3rd ed. (Pp. 416. 27s. 6d.) London: Henry Kimpton. 1947.

A synopsis with many diagrams of the elements of obstetrics.

*Collected Papers of the Mayo Clinic and the Mayo Foundation.* Vol. XXXVIII. Edited by R. M. Hewitt, B.A., M.A., M.D., et al. (Pp. 915. £3 3s.) Philadelphia and London: W. B. Saunders Company. 1947.

A collection designed primarily to meet the requirements of the general practitioner and general surgeon.

*A Textbook of Pathology.* By William Boyd, M.D., Dipl. Psych., M.R.C.P.Ed., F.R.C.P. 5th ed. (Pp. 1,049. £2 8s.) London: Henry Kimpton. 1947.

This well-known textbook includes new material on botryomycosis, giant-cell pneumonia, alloxan diabetes, renal anoxia, folic acid, and pathogenesis of poliomyelitis.

*Patología Digestiva.* Vol. II. Edited by B. V. Fuentes and A. Munilla. (Pp. 782. No price.) Buenos Aires: Espasa-Calpe. 1947.

The pathology, diagnosis, and treatment of disease of the alimentary tract; with summaries in English.

*The Appendix.* By R. J. McNeill Love, M.S., F.R.C.S., F.A.C.S. (Pp. 186. 12s. 6d.) London: H. K. Lewis. 1947.

A manual on the appendix, normal and diseased, based on an experience of over 5,000 appendicectomies.

*Nothing New Under the Sun.* By J. P. Lockhart-Mummery, F.R.C.S., M.A. (Pp. 178. 12s. 6d.) London: Andrew Melrose, Ltd.

Short articles for the layman on medicine and science; illustrated with woodcuts.

*Essentials of General Anaesthesia.* By R. R. Macintosh, M.A., M.D., F.R.C.S., D.A., and F. B. Bannister, M.A., M.D., D.A. 4th ed. (Pp. 358. 30s.) Oxford: Blackwell. 1947.

A textbook for the medical student and postgraduate.

*Vitamine e Bioregolatori.* Part I. By O. Carere-Comes. (Pp. 150. No price.) Turin: Edizioni Minerva Medica S.A. 1947.

An account of the vitamins.

*Practical Biology for Medical and Intermediate Students.* By C. J. Wallis, M.A. 2nd ed. (Pp. 396. 21s.) London: William Heinemann. 1947.

In four parts: Microscopical Technique, Elementary Biochemistry, Plant Biology, and Animal Biology.

*A Manual on Dental Metallurgy and Non-Metallic Materials* By E. A. Smith. 6th ed. (Pp. 391. 16s.) London: J. and A. Churchill, Ltd. 1947.

A general account of the metals and non-metals used in dentistry.

*Annual Review of Microbiology.* Vol. 1. Edited by C. J. Clifton, et al. (Pp. 404. 36s. or 56s.) Stanford, California: Annual Reviews, Inc. London: H. K. Lewis. 1947.

Includes papers on malaria parasites, bacterial metabolism, antibiotics, immunization, and respiratory viruses.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 27 1947

## MR. BEVAN'S GLOSS

The Council of the B.M.A. met on Dec. 17 to consider the Minister of Health's written reply to the document presented to him by the Negotiating Committee, and on the same day issued a statement to the Press which is recorded elsewhere in this week's *Journal*. The Minister has, in fact, published two statements. The second was a detailed reply to the points made by the Negotiating Committee. The first was in the form of an appeal to the individual doctor and is worth examination. "Hardly any major step," the Minister writes, "to better social services (in which doctors, above all, are interested) has provoked more misstatements or misunderstandings than the National Health Service Act." Mr. Bevan then goes on to attempt to clear "some of the more fundamental points which must be exercising many doctors' minds." In this appeal the Minister would seem to deny the reality of the well-grounded objections the medical profession has to certain important features of his Act. His appeal is in its general effect a misstatement of fact, made none the less a misstatement by the persuasive language in which it is couched. He says, for example, that there is no hierarchy of supervision, when the whole administrative structure of the Act is a pyramid of lesser hierarchies with the Minister himself the arch hierarch at the apex. He slurs over the existence of the Medical Practices Committee, which is to "supervise" or—to use plainer language—to control. He does not mention the fact that the chairmen of various administrative bodies from Local Executive Councils upwards are to be appointed by him. To state that the doctor is not "under orders" is to evade the plain fact that the Minister has set up a mechanism for distributing doctors, with facilities for appeal to him against the decision of the Medical Practices Committee. The Executive Council will propose, and the Medical Practices Committee will dispose—another synonym for "direct." The doctor, according to Mr. Bevan, is "not employed." Every family doctor in the public service will receive a basic salary, not through an insurance scheme but from public funds. At the meeting with the Negotiating Committee on Dec. 2 and 3 the Minister referred to the doctors in the new Health Service as "public servants." If one is a servant of the State in receipt of a salary, by what process of reasoning does Mr. Bevan reach the conclusion that doctors are "not employed"? It may be that the majority of doctors when they have to decide this issue may be content to be employed by the State as State servants, and once they have got used to the idea of being

paid partly by salary called basic they may become accustomed to being paid altogether by salary. It would be a logical sequence of events. It would be inevitable, however gradual. But if the medical profession should decide to take this step it should at least know exactly what it is doing, and should not be deceived by Mr. Bevan's misstatement if they are to avoid misunderstanding.

"It is the essence of a successful National Service," Mr. Bevan observes, "that both doctors and the Government co-operate in getting the nation as a whole to benefit by it." No one could agree more with Mr. Bevan than the Negotiating Committee, which through its six sub-committees has been discussing so many problems with the Minister's officers during the past year. But Mr. Bevan's idea of co-operation is to refuse to accept any one of the Negotiating Committee's arguments for amending the Act, although Mr. Bevan encouraged the Committee to resume discussions with the possibility of amendment in mind. The conflict between Mr. Bevan and the profession centres round one fundamental principle, and no assurance or gloss of interpretation from him can alter this fact. The National Health Service Act commends itself to the political party in power because it leads unmistakably to the eventual establishment of a whole-time State medical service. We must remember what Parliamentary spokesmen have themselves said. Mr. Somerville Hastings in an article<sup>1</sup> in 1939 wrote: "To sum up then, there is no rational stopping-place between the first incursion of the State into preventive medicine and a fully developed State medical service." That is the doctrine. During the debate on the Second Reading of the Bill in the Commons in April, 1946, Mr. Bevan, in reply to Mr. Reid's observation that he was "out for a full-time salaried service as soon as he feels he can impose that upon the country," made this prophetic statement: "There is all the difference in the world between plucking fruit when it is ripe, and plucking it when it is green." Mr. Reid pressed his point by quoting from the Labour Party's pamphlet published in April, 1943: "In the Labour Party's opinion it is necessary that the medical profession should be organized as a national full-time salaried pensionable service." Mr. Arthur Greenwood, then Lord Privy Seal, removed any doubts anyone may have had by stating: "What was published by my party in 1943... we of course stand by... and we shall continue to march on in the light of that policy." Mr. Bevan marches on.

A State medical service is something to which the medical profession has always been resolutely opposed, because it believes that the restrictions and frustrations of a State service geared to a top-heavy administrative machine would prevent that intellectual freedom which is so essential to medicine as a science and an art. No matter what his party, the Minister of Health is first and foremost a politician, whose decisions are largely governed by political ambitions and fears. The office of Minister of Health is for the politician a step up or a step down on the political ladder. To put into the hands of such a political figure such power over the destinies of medical men as the Minister now seeks is to turn the hands of the clock back—not forward. But since 1939 we have become so inured

<sup>1</sup> *Med. Q.*, 1939, 61, 167.

to being directed by this, that, or the other Government Department that we tend to accept it as the natural shape of things to-day.

The Minister states that he "is confident that the profession will join with him, as constructive and often properly critical partners, in getting it under way." As the Minister has refused to act as a result of proper criticism before the Act starts, how can the profession have any confidence that their collective voice will have any effect in the future unless it happens to be an echo of their master's voice? We know well how reluctant medical men in the Public Health Service or in the Municipal Hospital Service are to voice their criticisms or, having voiced them, to let their names appear in the columns of this *Journal*; we meet their difficulties when possible by allowing them to remain anonymous. What real freedom of expression of opinion will there be under Mr. Bevan's Act when the consultant and specialist are employed in a State hospital and the general practitioner is receiving his salary from State funds? Mr. J. Johnston Abraham, an eminent medical man who speaks with the authority of one connected with a well-known firm of publishers, points out in our correspondence columns this week that no official employed by the Ministry of Education is allowed to write educational books unless express permission has been given, and this Ministry, he observes, claims the royalties earned, on the ground that the authors are full-time officials. The Minister of Health, no doubt, will retort that we are raising another bogey and will give another assurance. But we have here an example of what happens, and Mr. Abraham is not overstating the case when he writes: "In medicine such a situation would be disastrous, for articles or books criticizing official lines of treatment might be frowned upon, held up, or even suppressed." To use a phrase the Minister is fond of, "the very essence" of medicine is freedom. The National Health Service Act is the first and most important step towards denying the medical profession this freedom. If the medical profession does not hold this to be an absolute good necessary to its fruitful evolution, or if it does not believe that its real freedom is threatened by the Health Service Act, then it will presumably accept Mr. Bevan's invitation to co-operate with him in starting the new Service next July. If, however, the medical profession, after deep reflection upon "the essence" of Mr. Bevan's proposals, concludes that this Act is the first and irrevocable step towards a whole-time State medical service, then it must have the courage and the integrity of mind to refuse to serve under the Act until it has been amended in those particulars which the profession holds to be essential to its continued existence as a body of free men.

## LESSONS OF THE POLIOMYELITIS EPIDEMIC

Three contributions to this issue of the *Journal* give further proof that the epidemic of poliomyelitis which is now subsiding has added to our knowledge of the disease. The epidemic was unusual for this country not only in its severity but in the uncommon syndromes which it caused. The presence of an epidemic leads, of course, to the recog-

nition of many bizarre forms of the disease which might otherwise be misdiagnosed, and to the notification of transient and benign forms which at other times remain undiagnosed. McAlpine and his colleagues (p. 1019) have recognized this, and they draw attention to certain forms of the disease which they classified as either abortive or non-paralytic according to the absence or presence of minor signs of involvement of the central nervous system. These cases have been common in the present epidemic, and Murray (p. 1028) recognizes similar types but would prefer to divide the non-paralytic cases into clinical and subclinical categories, thus avoiding the term "abortive," which is misleading. He emphasizes the important part played by these cases in the spread of infection, and says that Casey's experience in the Chicago epidemic of 1945 "does seem to indicate that poliomyelitis, during an increased incidence of the disease, is a mild, widespread, highly communicable disease particularly of young children, leaving no paralysis." Non-paralytic and often ambulant cases in fact play a much greater part in the spread of poliomyelitis than the frankly paralytic patients immobilized in hospital.

Unfortunately, advance in our knowledge of the epidemiology of the infection in the British Isles has been limited by the complete lack of the necessary experimental animals—primates. This shortcoming has been redressed in some measure by the results of experimental work already published by Bodian,<sup>2</sup> Sabin,<sup>3</sup> and others in America. It is still too soon to assess the epidemiological lessons of the present epidemic, but much may be learnt from the two large-scale investigations now in progress.<sup>4</sup>

The clinician's main interest has been in the recognition of the unusual cases and in their treatment. The Ministry of Health<sup>5</sup> quite early in the outbreak indicated some of the neurological changes which might be seen in different cases. Kelleher,<sup>6</sup> in an article specially contributed to the *Journal*, quoted a number of cases in which there was early involvement of the cranial nerves. Some of McAlpine's cases showed complicated supranuclear ophthalmoplegias, sensory loss, widespread involvement of bulbar nuclei, and even transverse myelitis.

Scheinker's<sup>7</sup> important study of the histopathology of the central nervous system clearly revealed how easily these widely different clinical pictures may arise. Study of the whole nervous system of six cases confirmed the widespread inflammatory response of the tissues associated with localized parenchymal destruction of motor elements which has been described previously. Scheinker then showed that these two changes are independent. The first is a response to the invasion of the whole nervous system by the virus, while the second gives evidence of its specific lethal effect on motor neurones.

Ritchie Russell considers elsewhere in this issue (p. 1023) the physiological state of the motor neurone at the time of the invasion in relation to the degree of paralysis which

results. The basis of this work was the interesting experiment of Howe and Bodian<sup>8</sup> which showed that anterior horn cells that had had their peripheral extensions sectioned shortly before were immune to experimental infection with the poliomyelitis virus. Clinical observers have commented upon the association of great physical exertion in the pre-paralytic phase of the illness with a severe degree of paralysis, but no attempt seems to have been made to investigate this point statistically. Russell has studied carefully 44 patients who were convalescent from poliomyelitis and who were old enough to describe in detail their symptoms and their activities in the first few days of the disease. His conclusion, which appears to be statistically sound, is that muscular work at the time of neuronal invasion is closely related to subsequent neuronal destruction. The stoical patient who struggles on becomes helpless; those who retire to bed at the onset of the first symptoms do well.

If Russell's preliminary conclusions are confirmed, early diagnosis will become more important than ever and it will be necessary to insist on complete rest in bed right from the start of what the patient may deem a trivial illness. According to Russell, the so-called meningitic symptoms appear in nearly all cases during the pre-paralytic stage and are often more suggestive of involvement of the nerve roots than of the meninges. The Middlesex workers point out the difficulties in differential diagnosis at an early stage of the disease; but whether the patient's first complaint is of pain resembling that which occurs in epidemic myalgia or of true meningitic symptoms suggesting the possibility of a benign type of lymphocytic meningitis, any continuance of physical activity would be unwise. Diagnosis at an early stage can be made only by the general practitioner, but it is clear that such early diagnosis is of the utmost importance for the patient's future as well as for the limitation of infection.

### MISTLETOE

"Cure Guaranteed" was the notice that Dr. Schutzmacher<sup>1</sup> displayed in his surgery window and which made him a wealthy man. Surely the drug that he most favoured in his prescriptions must have been extract of mistletoe, for physicians and laymen throughout the ages have acknowledged that it cures every disease, is an antidote to all poisons, and promotes longevity, prophetic dreams, good fortune, and happiness. Gerard<sup>2</sup> described in 1597 how "if it be used in outward applications it draweth humors from the deepest and most secret parts of the body," and it was commonly prescribed to heal wounds, especially those sustained in the hunt. The disease for which it has always been regarded as pre-eminently beneficial is epilepsy, for clearly a plant that clings tenaciously to the upper branches of trees without ever being blown to the ground or growing there must be a specific remedy for the "falling sickness." For that reason sprigs were tied round the necks of children in Wales and Brittany.

Unfortunately its powers seem to have waned to-day, perhaps because we have lost the art of preparing what was once so efficacious a remedy. The Druids, who venerated above all things this evergreen parasite and the oaks upon which it seldom grew, procured it with ritual circum-spection. According to Pliny<sup>3</sup> a priest arrayed in white climbed the tree and cut down the mistletoe with a golden

sickle, catching it in a white cloak as it fell. On no account might it be severed from its host with iron, nor was it allowed to touch the ground, which was unclean and would have contaminated it—a prohibition familiar enough in the era of asepsis. Whatever its powers may have been, the *B.P.C.* praises them cautiously, pointing out that, since its active principle is a vasodilator, it has been administered to lower blood pressure and to relieve precordial pain; it mentions, however, that "it has been found useful in cases of hysteria and chorea."

The science of medicine has changed more than has popular medicine since Anglo-Saxon and mediæval times, and it no longer allows us to expect each newly discovered drug to be a panacea, nor prompts us to search for one. The quest of the alchemists over many centuries for the elixir vitae that should cure all maladies of body and mind appears to us now as a barely intelligible confusion of thought—the passionately misspent youth of chemistry. But lest we scorn those apparently sterile crucibles we might bear in mind T. S. Eliot's reply to the observation that "the dead writers are remote from us because we know so much more than they did."—"Precisely, and they are that which we know." Medical men by means of their training come to know the dead in that sense, and for that reason the alchemists and their ways of thought seem remote from us. Knowledge of history is both an introduction and a parting. Among our patients, however, we find many who still travel these primitive ways of thought, for advertisements continue to appeal successfully with their offers of magical cure-alls: a particular ointment or lotion or physic will both heal our skins and bring us romance. The panaceas are still with us, even if rejected by medical men. The mental attitude that leads to belief in them is not confined to primitive minds, it is merely misused by them; for philosophers and mystics have discerned behind the many appearances the one reality, while peasants have confused the two. If an essence of healing can be conceived of underlying the diversity of remedies, surely that elusive virtue can be imparted in a cunningly prepared decoction, dispersing the blemish, making the crooked straight, and bringing happiness under the oak tree. That golden bough, the mistletoe, is still called "cure-all" in the modern Celtic speech of Wales, Scotland, Ireland, and Brittany.<sup>4</sup>

Though usually forbidden as a decoration in churches because of its pagan association,<sup>5</sup> it has always been indispensable in the home at Christmas time, and we understand that the Board of Trade has relented so far as to allow the importation of "limited quantities" from France this year. In one capacity, at any rate, mistletoe remains a panacea. Hanging from the ceiling—"to the imminent peril of all the pretty housemaids," as Washington Irving<sup>6</sup> remarked in the more spacious days of a century ago—it is still the emblem and instigator of love; and poets and psycho-analysts unite in agreeing that Eros can cure all our ills. We would therefore commend infusion of mistletoe as a certain remedy for some of the disorders that seem to be reported with increasing frequency, such as depersonalization and vagitus uterinus. We have yet to hear of its failure to cure these conditions. At this festival may it diminish demands for certificates, telephone calls, and broken nights, and at least act as a sweetener of the austerity prevailing in our new-model Merry England.

## SYNTHETIC VITAMIN A

The significance of "fat-soluble A" as a factor necessary for the growth of rats was recognized by MacCollum<sup>1</sup> more than thirty years ago. Subsequently vitamin A was second only to vitamin D in having its biological activity explained chemically. Steenbock<sup>2</sup> traced a close parallelism between vitamin A and the yellow colour in fruits and vegetables. Then in 1928 Euler<sup>3</sup> found that pure carotene possessed biological activity. Moore<sup>4</sup> demonstrated that carotene is the precursor of true vitamin A, which is a colourless substance produced only by animals. Karrer<sup>5</sup> confirmed that vitamin A was a carotenoid derivative, and suggested the structural formula which later work has vindicated. There has, indeed, been no serious challenge for the last sixteen years to the conclusion that vitamin A is essentially the  $\beta$ -carotene molecule cut in half and converted from a hydrocarbon into an alcohol. It consists, therefore, of a  $\beta$ -ionone ring to which is attached a long polyene side-chain terminated by the hydroxyl group.

This chemical structure, although relatively simple, indicates a high degree of instability towards oxidation and various chemical reagents, so it is not surprising that other vitamins, such as B<sub>1</sub>, C, E, K, and riboflavin, should have been isolated, identified, and synthesized before vitamin A. The slow rate of progress cannot be blamed on lack of effort. Karrer in Switzerland and Heilbron<sup>6</sup> in Britain both ranked among the world's leading organic chemists, have devoted much energy and ingenuity to the problem, and have greatly extended our knowledge of the chemical properties of the vitamin. Other workers have had varying degrees of success in either synthesizing the vitamin in impure form<sup>7,8</sup> or synthesizing biologically active derivatives of the vitamin, notably the corresponding methyl ether.<sup>9-11</sup>

During the past two years, however, such rapid advances have been made by two young Dutch chemists, van Dorp and Arens, that a successful synthesis of vitamin A on a manufacturing scale seems at last in sight. Their first success was the synthesis of the carboxylic acid corresponding to vitamin A.<sup>12</sup> This new derivative is said to be no less active than natural vitamin A when administered orally as its sodium salt.<sup>13</sup> It differs from all other forms of the vitamin and its precursors in failing to produce stores of vitamin A in the liver when given to rats in great excess of the physiological requirement.<sup>14</sup> It is also claimed that the acid is only slightly less active when injected subcutaneously than when given orally,<sup>12,15</sup> which suggests that it might be valuable in the treatment of patients with impaired intestinal absorption.

More recently the same workers claim in a preliminary communication that they have synthesized vitamin A itself.<sup>15</sup> Starting with  $\beta$ -ionone, a substance readily obtainable from vegetable sources, they built up the C<sub>11</sub> ketone corresponding to vitamin A by a procedure which had previously been found successful. This compound was next

treated with ethoxyethylene magnesium bromide to form a C<sub>22</sub> ketone. Partial hydrogenation of this product, followed by rearrangement and hydrolysis by means of hydrochloric acid, caused the loss of two carbon atoms, with the formation of the C<sub>20</sub> aldehyde of vitamin A. Spectroscopic tests indicated that this material was identical with the aldehyde obtained by the oxidation of natural vitamin A. Reduction with aluminium isopropoxide gave vitamin A itself, although not yet in purified form. While we must await a detailed account of this ingenious synthesis before assuming that this is the last word, it is obvious that the successful production of pure vitamin A, at least on a laboratory scale, cannot be long delayed. Great credit is due not only to our Dutch colleagues but to all who have preceded them in writing this long and difficult chapter in nutritional research.

## INTRA-ARTERIAL PENICILLIN

The intramuscular injection of penicillin is the most wasteful method of drug administration known; only a minute proportion of the dose reaches the site of a localized infection. Local application, while much more economical, is effective only when an infection is superficial or involves the walls of a closed cavity. A kind of compromise between these two methods is the injection of penicillin solution into the artery supplying an infected area. First employed by Ribeiro, this method has been tried by several other surgeons, and is reported on favourably by J. O. Shaffer,<sup>1</sup> who maintains that only in this way can the drug be enabled to penetrate into certain types of infected tissue. That material injected intra-arterially escapes from the artery into its area of supply and remains there he has proved by injections of radioactive phosphorus, the distribution of which was subsequently followed with a Geiger counter. A series of such experiments enabled him to show that the highest local concentration was obtained by making the injection while a sphygmomanometer cuff was applied to the limb at a pressure of 80 mm. Hg; this is in practice retained in position for 10 minutes after the injection. The dose of penicillin usually given, whether into the brachial or the femoral artery, is 50,000 units in 10 ml. of saline; one or two such doses are given daily. Forty patients have been so treated, some receiving many injections, without any untoward accident. Shaffer gives accounts of 17 cases, a number of which had been given penicillin in ordinary doses intramuscularly without effect. A large proportion of these were examples of diabetic gangrene: presumably tissue so affected is a special example of an area not reached by penicillin given in the ordinary way, owing to its poor blood supply. Very rapid subsidence of inflammatory changes was usually observed, and similar effects are claimed for the treatment of ordinary cellulitis and even acute osteomyelitis.

This method is evidently worthy of further study, both from the point of view of the scope of its clinical usefulness, and experimentally with a view to finding out what concentration of penicillin can be attained in the infected area and for how long. It should not be difficult to determine how much penicillin escapes from an artery when venous return is occluded for 10 minutes; if in fact any substantial proportion escapes, the local concentration will certainly be much higher than that attained by any other method. But for the comparative difficulty of intra-arterial injection and its painfulness, to which Shaffer does not allude, this might be the ideal method of treating septic conditions of limbs when frequent intramuscular injections are impracticable.

## MORPHINE AND DUODENAL SECRETION

The fact that morphine causes a varying degree of spasm in the 'terminal portion of the common bile duct' is now becoming generally known, and it is recognized that the use of morphine is undesirable after operation on the gall-bladder because of the pain caused by the rise in intrabiliary pressure. Lagerlöf<sup>2</sup> has now published observations on the effect of morphine on the pancreatic secretion in man. He collected the duodenal secretion in patients who had undergone cholecystectomy, stimulating a flow of juice by injecting secretin intravenously. He then compared the juice with that obtained when secretin and morphine were injected together. The duodenal juice consisted of both pancreatic secretion and bile. The injection of morphine was observed to result in a diminished volume, a diminished enzyme (amylase) concentration, and a diminished bilirubin concentration. In spite of the smaller volume of juice, the concentration of amylase fell to one-fifth to one-tenth of the concentration after secretin was given alone. The fall in bilirubin concentration was great enough to render the duodenal juice colourless for 20 minutes in two of the patients. Lagerlöf emphasizes that this change occurred in patients whose gall-bladders had been removed and in whom the injection of secretin alone did not interrupt the flow of bile. In normal subjects the bile is diverted to the gall-bladder and does not enter the duodenum. Consequently Lagerlöf concludes that the fall in bilirubin in the duodenal juice which he observed after giving morphine was due to contraction of the sphincter of Oddi. The patients also suffered from attacks of pain after receiving the morphine. The amount of bicarbonate in the duodenal juice after the injection of morphine was lowered though not so much as the amount of amylase and of trypsin, and Lagerlöf suggests that there was a decreased delivery of pancreatic juice to the duodenum.

It is evident from these observations that the common practice of prescribing morphine to relieve the pain of acute pancreatic disease needs reconsideration. The most active analgesic which does not cause spasm of smooth muscle, but on the contrary relaxes the spasm, is pethidine. Its use is still limited despite its relatively powerful action, apparently because its analgesic effect is not uniform in different individuals. Some medical men observing this have concluded that pethidine is unreliable, not realizing that patients vary just as much in their response to morphine.

## NEW WAYS OF TREATING URAEMIA

Attention has previously been called in this country<sup>1,2,3</sup> to the work of Kolff on the treatment of uraemia by means of a dialysing apparatus, the "artificial kidney." Blood is led from the heparinized patient through a long cellophane tube wound round a drum which rotates in a bath of specially prepared saline. By means of this ingenious machine, which was developed under great difficulties in occupied Holland, large amounts of urea can be separated from the blood in cases of uraemia; other toxic changes, such as a high potassium and low alkali reserve, can be corrected as well. Thus in one instance the blood urea was reduced by the artificial kidney from 425 to 140 mg./100 ml. and 146 g. of urea were removed by the rinsing fluid in six hours. Kolff has now published in full his experience with this method up to the present time.<sup>4</sup>

<sup>1</sup> *British Medical Journal*, 1947, 2, 216.

<sup>2</sup> *Lancet*, 1946, 2, 720, 726.

<sup>3</sup> *Ibid.*, 1947, 1, 106.

<sup>4</sup> *New Ways of Treating Uraemia*, 1947, J. and A. Churchill, London. Price 10s. 6d.

Kolff also describes a technique for peritoneal lavage. The major difficulty here is that large quantities of sterile fluid—about one litre per hour for 36 hours—are required to achieve the same result as that brought about by the artificial kidney in six hours. There is, too, a considerable risk of peritonitis, though Kolff's method, which he describes in detail, avoids any exposure of the sterilized saline solution. Lavage through isolated loops of ileum is also being considered. These are all technical advances which Kolff has explored with great skill. In an almost hopeless series of patients there are now seven survivors who might have died but for this new type of technical medical intervention. Treatment by the artificial kidney is most likely to be successful in uraemic patients whose kidneys are not too grossly damaged.

In the last chapter of his book Kolff gives a short account of the recent work by his fellow-countryman, Prof. Borst, on the treatment of uraemia by a non-protein high-calorie diet (200 g. butter and 200 g. sugar daily). On this diet the protein breakdown in the body is reduced considerably below the supposed minimum of 45 g. daily, and the daily excretion of urinary urea may be no more than 1-3 g. This method is of special value in the treatment of the more chronic forms of uraemia; the acute disorders may be better met by active technical procedures. We look forward to hearing more from our Dutch colleagues on these interesting developments, and meanwhile they are to be congratulated on their ingenuity and energy in tackling what was often regarded as an irretrievable medical disaster.

## TETRAETHYLAMMONIUM BROMIDE

The demonstration by Acheson and Moe<sup>1</sup> that the tetraethylammonium ion blocks the transmission of nervous impulses through autonomic ganglia in animals has excited interest and has led to extended observations on its action and possible uses in man. The bromide or chloride salt may be injected intravenously as a 10% aqueous solution in doses of 200 to 500 mg., or intramuscularly in doses not exceeding 20 mg. per kilo body weight. The autonomic ganglionic block is complete and affects both the sympathetic and parasympathetic systems. A recent report by Lyons, Moe, and others<sup>2</sup> summarizes observations made on over 400 subjects.

After a suitable intravenous injection autonomic activity virtually ceases, but peripherally acting drugs like adrenaline and acetylcholine may still exert their effects. On the sympathetic side the most important result is the release of vasoconstrictor tone. The blood pressure falls, especially in hypertensive subjects, and there is marked orthostatic hypotension. The venous pressure also falls, and the blood flow in the extremities is increased and the skin temperature rises. The heart rate and cardiac output—measured with the ballistocardiograph—are also increased. On the parasympathetic side the gut and bladder are temporarily paralysed; salivary secretion is diminished, and sweating ceases.

The drug has already proved useful in the treatment of vasospastic states and should be particularly valuable in the treatment of peripheral embolism. Its effects on hypertensive patients harmonize more or less with the results of later lumbodorsal sympathectomy, but no linear correlation has been established. It has proved at least the equal of all other methods designed to release vasomotor tone in order to predict the results of sympathectomy in cases of peripheral vascular disease. For obvious reasons it is an impracticable therapeutic agent, but it should prove an asset to research workers in many fields.

## AVOIDABLE MENINGITIS

*Memorandum drawn up by the Public Health Laboratory Service and the London Sector Pathologists' Committee*

Every operative procedure entails some risk to the patient, but in simple operations such as spinal puncture the risk ought to be practically negligible. Meningitis occurring after the withdrawal of cerebrospinal fluid or the administration of a spinal anaesthetic is a grave reflection on the methods used in many hospitals, for these "accidents" can be avoided by the adoption of a simple and reliable technique. That such a technique is not in fact universally employed is attested by the number of cases of avoidable meningitis reported in the literature during the past few years. Furthermore, as Garrod (1946) points out, "There is a natural reluctance to publish anything which may appear discreditable. . . . It is therefore probable that meningitis following spinal anaesthesia has been far commoner than the literature of the subject would suggest." This statement is endorsed by surgeons and anaesthetists whenever the subject is discussed.

### Nature and Sources of Infection

This memorandum is not concerned with meningitis secondary to some primary infective focus already present in the patient at the time of operation. It refers solely to meningitis that results from the direct inoculation of micro-organisms into the spinal canal. The organisms most frequently incriminated are *Pseudomonas pyocyanea* and related organisms which can multiply in water at room temperature; less often staphylococci and other skin contaminants may be responsible. Some of the water bacteria fail to grow in ordinary culture media incubated at 37° C.; hence many cases have been diagnosed as irritative or aseptic meningitis which were probably the result of bacterial infection of the meninges. Organisms normally regarded as non-pathogenic may produce infection if they gain access to the very susceptible meninges.

The sources of contamination may be listed as follows: (1) apparatus inefficiently sterilized, or contaminated during use; (2) "sterile" water or saline used to rinse the apparatus; (3) hands of operator and assistants; (4) skin of patient; (5) anaesthetic, antibiotic, or other solutions.

### Preventive Measures

The ideal would be to adopt the full aseptic ritual of a surgical operation for every spinal puncture. In many cases the time and place render this impossible. The following recommendations are therefore offered, not necessarily as ideal procedures but as practical methods applicable in nearly all circumstances.

**Apparatus.**—If facilities are available, all apparatus, including manometer, should be enclosed within suitable containers and sterilized either by autoclaving at 15 to 20 lb. per sq. in. (1.04–1.37 kg. per sq. cm.) pressure for 20 minutes or by dry heat at 160° C. for an hour. The complete outfit can then be held ready for use at any time. If dry heat is used, the rubber tubing of the manometer should be sterilized by boiling. For syringes and needles dry heat is preferable but ordinarily necessitates the use of all-glass syringes. (Glass syringes with metal nozzles which will withstand dry heat at 160° C. for two hours are now being manufactured.) Full details of these methods together with recommendations for a hospital syringe service are given in the M.R.C.'s War Memorandum No. 15 (1945) on "The Sterilization, Use, and Care of Syringes."

If autoclaving or dry-heat sterilization cannot be employed, all apparatus should be sterilized immediately before the operation by boiling for 5 minutes, preferably in distilled water. A sterilizer with a perforated lift-up tray should be used; at the end of boiling the tray is removed, placed in the inverted lid covered with a sterile towel, and left to cool. In the occasional emergency which may arise in the patient's home a perfectly clean saucepan with a lid may be used. After boiling, the water should be drained off and the saucepan left with the lid on until cool. Methods of chemical disinfection such as soaking in spirit should not be used.

**"Sterile" Water and Saline.**—These probably constitute the greatest source of danger. Hospital supplies are frequently

contaminated either from inadequate sterilization initially or from contamination during previous use (Smith and Smith, 1941). Thus the Winchester bottle of "sterile" distilled water or saline, used repeatedly until empty, has frequently been incriminated as the source of water bacteria found in contaminated or infected cerebrospinal fluid. If apparatus is sterilized as recommended above, rinsing and cooling solutions become quite unnecessary and their use should be abandoned.

**Hands of Operator.**—The operator should scrub up as for a major operation, or alternatively should don dry sterile surgical gloves. When gloves are not available it is important that his hands be dry before he handles any apparatus; this may be accomplished by rinsing with industrial spirit and/or drying with a sterile towel. Where needle and syringe have to be assembled, the needle should be handled with sterile forceps. From this point onwards the operator should touch nothing except the sterile instruments and the skin of the patient until the operation is finished. The trocar when withdrawn should be laid on a sterile towel; otherwise it may infect the spinal fluid if it is introduced again to clear the needle.

**Skin of Patient.**—Thorough washing with soap and warm water followed by thorough, not perfunctory, swabbing with tincture of iodine or 70–90% alcohol will leave little risk of contamination of the needle by the patient's skin. The area treated should be the entire area exposed and the skin should be quite dry before puncture is made.

**Anaesthetic and Antibiotic Solutions.**—No cases of meningitis have been traced to the presence of bacteria in anaesthetic solutions contained in sealed glass ampoules. Such ampoules are preferable to rubber-capped bottles intended for repeated use. The sterilization of the outer surface of an ampoule is difficult and attended with such pitfalls that it is better not to attempt it. The ampoule should be opened, after swabbing the neck with 70% alcohol applied with sterile swabs, by an assistant whose hands have been scrubbed and dried. It may be held in a sterile towel or piece of sterile lint. The operator must then introduce the needle of the syringe into the ampoule without fouling the mouth. Other forms of container should be avoided except where absolutely necessary. If a rubber-capped bottle has to be used, the cap should be thoroughly swabbed with 70% alcohol or tincture of iodine and held in a sterile towel by the assistant. The bottle should be returned to the central sterilizing depot after use each day.

The intrathecal injection of antibiotics such as penicillin and streptomycin demands the same high standard of aseptic technique, and all precautions should be taken to ensure that the solutions themselves are sterile.

### Reporting of Cases

The general adoption of the measures recommended here would without doubt reduce the incidence of "accidental" meningitis but would not close every possible loop-hole for infection. Further safeguards can be found only if cases are thoroughly investigated as and when they occur and with the employment of specialized bacteriological methods. The Public Health Laboratory Service will willingly co-operate with the hospital pathologist or other officer in carrying out such investigations as are required.

Gratitude is expressed to Sir Hugh Cairns and Prof. Wilson Smith for the help they gave in the preparation of this memorandum.

The Pottery (Health) Special Regulations, 1947, issued on Oct. 1 control the use of lead, flint, and quartz in industry. After the expiry of one year from the making of the regulations only leadless or low-solubility glaze may be used in a factory to which the regulations apply in the manufacture of pottery other than glazed tile. A period of two years from the making of the regulations shall apply to factories where the manufacture of glazed tiles was suspended after Sept. 3, 1939, and resumed under the same occupation not later than one year after the making of the regulations. After three months from this date the use of ground or of powdered flint or quartz is prohibited for certain purposes except in slurry or paste.

"Well, what damn' fool excuse for extra rations are you going to make this time, Mrs. Lumbumbago?"

A MERRY CHRISTMAS

The Editor and his staff wish readers of the *B.M.J.* a Merry Christmas. In our highly professional columns there is little room for conscious humour, though the compositor occasionally breaks through the editorial defences, as on the occasion when he set the heading to a short paragraph as "Psychotherapy as a cause of illness" instead of "Psychoneurosis. . . ." And there was a lamentable lapse of the pen when we allowed a contributor, in his description of a gadget, to write: "In the hands of my colleague, Dr. X, this has turned out to be completely foolproof." The penultimate sentence of a long leading article on a controversial matter began, "These are the facts we have to face." The compositor, no doubt, felt he was removing all ambiguity when he substituted the word "fads" for "facts." Humbled by his criticism we nevertheless stuck to our guns and restored the original word.

There is no bright piece of news to cheer the hearts of doctors this Christmas. We have our Minister of Health, and he has his Act. The witch-doctor, happy anarchist, had no Minister, no Ministry, no awkward Acts of Parliament, no doctor's dilemma. Intense individualist, he flourished in a state of complete insecurity. In asking Giles, the famous cartoonist of the *Sunday Express*, to brighten the Christmas number of the *B.M.J.* with a cartoon we described to him some of the current frustrations of doctors. His comment appears on this page.

If there is a witch-doctor at the core of the practitioners of the art and the science, medicine nevertheless advances, and we take pride and comfort in this fact. So that readers

may be right up to date with the more recent advances we print below some of the most outstanding that have been recorded in the past weeks.

RECENT ADVANCES

Special Specialist

When asked by the chairman of East London Juvenile Court to-day the title of a book he had stolen, an 11-year-old boy replied: Why I am a Christian. He was remanded in custody for a special psychiatrist's report.—*Evening Standard*, Dec. 8, 1947.

Hints to the Newly Qualified

Look out for false hips of buckram (£1 a pair), canvas frills sewn under the waistline, boned hip seams, and padded pockets for hip fullness.—*Evening Standard*, Nov. 27, 1947.

Co-education ?

Heathfield School, Harrow, is now a Public [sic] Independent School with a Board of Governors under the chairmanship of Sir Alfred Hurst, K.B.E., C.B. Miss Norris is still head mistress.—*The Times*, Oct. 25, 1947.

Caught in the Slips

A profusely illustrated account of the ball-bladder, its diseases, and the treatment of them.—*British Medical Journal*, 1947, 2, 299.

Calories and Levitation

Other simple methods of giving energy to the human body are walking barefooted on wet or dewy grass, wet stones or concrete, paddling in sea or stream, and smelling flowers. . . . A tired man or woman really crawls along supported from

the ground upwards. As an experiment I suggest that such a person should visualize that he is supported from above his ears by a chain which lifts him so that his feet just touch the ground.—*Sunday Express*, Nov. 30, 1947.

### Rabbit Pie

Dr. F. R. SELBIE has now succeeded in transmitting the Shope papilloma virus to its 9th passage in domestic rabbits. This has been done with the aid of contaminating micro-organisms; but just which ones are responsible has yet to be decided.—*Lancet*, 1947, 2, 835.

### Wedding of the Year

#### MARRIAGES

## ORGANIZING A GERIATRIC DEPARTMENT

BY

L. COSIN, F.R.C.S.

Medical Superintendent, Orsett Lodge Hospital, Essex C.C.

There can be no doubt that the aged sick and infirm need more skilled medical attention than is at present available; the provision of this would lead to improved classification and increased rehabilitation, and greatly reduce the number of old people who are bedfast.

To arrive at these results the available hospital accommodation will have to be reorganized to provide:

(1) *Acute geriatric wards*, where most patients will have their investigation and treatment completed in less than six months. (2) *Long-stay annexe wards for the permanently bedfast*. (These two types of wards will require a full nursing service.) (3) *Long-stay annexe wards for frail ambulant patients*. It is surprising how great a proportion of patients previously considered permanently bedfast can occupy this type of ward for a large part of their stay in hospital. Even patients with malignant disease are happier and feel better when they are able to do something for themselves, and are out of bed for part of the day. (4) *The "resident home" type of accommodation for the more robust patients*. Ultimately it is hoped that this type of patient will be moved out of the immediate hospital environment to a small hostel or resident home provided by voluntary bodies or the local authority. Considerable economies can be effected in nursing staff in these last two classes of patient.

### The "Resident Home" Ward

With wards closed owing to the present nursing shortage it should be easy to provide one small unit for the resident home. As soon as a sufficient number (twelve to twenty) of ambulant patients are available the resident home ward could be pro-

vided with one part-time nurse to smooth out the administrative difficulties of the first six months. Later she could be transferred to the "long-stay annexe" ward for frail ambulant patients. One or two nursing orderlies would usually be needed to help the nurse in charge. I prefer no night supervision of the resident home ward except the routine three visits by the night Superintendent, as such patients should be well able to look after themselves. If any nursing treatment, apart from minor dressings, is required patients should be moved back to the "active geriatric ward" for a short period. It is inadvisable to allow a period of more than a day or two in bed, as full nursing supervision should not be provided. Patients who have spent four to six weeks in the resident home ward under such a regime may be considered suitable for a resident home away from the hospital.

At the end of six months resident homes for both males and females should be filled, and another ward be taken over for this work, as probably no outside resident home would be available. By then the part-time nurse and orderlies would have settled down to their routine and the unsuitable patients have found their most suitable environment. No great amount of geriatric rehabilitation would have taken place, but a medical survey would have established the number of patients permanently bedfast, the number of patients who would most likely improve from a short course of physiotherapy and re-education in walking, and probably a larger number who would require more treatment and physiotherapy before recumbency could end.

### Long-stay Annexes

The staffing of a long-stay annexe ward for the frail ambulant cases should not be difficult, for only one full-time nurse or sister-in-charge will be required for twenty to thirty patients, with one part-time nurse for off-duty periods. The rest of the staff would consist of male or female ward orderlies. One orderly for each six patients is the minimum required, while a night orderly service must be provided.

It should now be possible to provide one large ward, at first subdivided by curtain partitions, as the long-stay annexe for the permanently bedfast, and it is here that adequate staff must always be available. This ward should have a large number of senior part-time mature nurses, whose outside interests obviate the sapping of morale by their hospital duties and who are able to offer the best service to these most unfortunate people. We must keep our young nurses and trainees in the active geriatric wards, where progress towards recovery is the keynote of treatment and interest in the patients is not stultified because they are permanent.

Dr. Marjory Warren (1946) has drawn attention to the great advantage of segregating permanently incontinent patients; similar provision should be made for the mentally confused, many more of whom should be ambulant. The frequent use of cot-beds and narcotics in restraining the restlessness of old people kept recumbent for long periods is too common to be coincidental. Now cerebral vascular disease has several components, of which the cerebral oedema accompanying the subacute and acute periodic ischaemias is prominent. If to this composite picture we add the cerebral oedema of recumbency and the frequent presence of a high serum bromide, as well as the restlessness due to a disorientated old person trying to get out of bed to empty his bladder or bowels, we can picture what happens. How often have we seen a pitched battle fought in the ward between several nurses and an elderly man more aware of his bodily needs than are his attendants? On the few occasions when the patient wins he disgusts the staff by defaecating or micturating at the side of his bed. The picture of a distressed patient struggling to prevent the soiling of his bed while the nursing staff are struggling to keep the bed soiled would be amusing if it were not so often repeated.

Get these patients up into a suit of clothes; sit them up to the table at meals; take them to the lavatory at frequent intervals. It will then soon be found that those capable of walking to the lavatory unaided will do so and relearn the regular habits of childhood; others will need assistance from orderlies. In this way much of the incontinence of recumbency will be cured, for it is largely due to faecal retention with overflow. For other patients it may be found necessary to give an enema once or twice a week. By these means the regular bedpan

rounds, four-hourly linen changes, and routine "back" rounds are completely eliminated. The nocturnal quiet of a ward under such conditions must be seen to be appreciated.

The immediate difficulty of staff shortages will again be mooted; but here also male or female orderlies under the supervision of one or two part-time nurses will provide invaluable help.

I have described this clinical picture at length as an example of failure to accept the degree of physical disability as the indication for permanent bedfastness. It has been my experience that far too many mild cases of senile dementia and cerebral arteriosclerosis were left needlessly in bed, thereby throwing extra work on nurses.

The bathing of these patients can be organized on a team basis on one morning a week. By the use of two orderlies for bathing—one for drying, and one or two to run a shuttle service with wheel-chairs from ward to bath and back—some thirty patients can be dealt with in four hours. Further economy can be effected by a team of two following up and making the beds.

The medical profession has for too long cast its less pleasant responsibilities upon an uncomplaining nursing staff; we must now reconsider the part our depleted nursing services are to play if they are to be used efficiently. We must consider ways and means of saving nurses' time.

### Medical Staff

Three factors that will control geriatric care in the next few years are the persistent shortage of nursing staff, the variable conditions prevailing in municipal hospitals, and the lack of doctors and physiotherapists trained in geriatrics. An immediate solution of this problem everywhere cannot, therefore, be contemplated, but it will be possible to organize a small number of efficient geriatric departments where aged patients can be properly treated and rehabilitated, so that nearly 50% can either be sent home or be given accommodation near the hospital and not require a full nursing service.

We may then concentrate our nursing and physiotherapy staff upon active geriatric wards, where rehabilitation may take up to one year but in most cases should not exceed six months. A geriatric department in a district hospital should comprise:

1. *A general physician*, who should be experienced in geriatrics, with available pathological, radiological, and electrocardiographic departments. I am making no plea for a new specialty or a new status. Geriatrics differs in no wise from general medicine, except that greater attention must be paid to the problem of multiple pathologies and their effect upon the vascular system as a whole. The medical aphorism that a man is as old as his arteries is the basic fact to which the geriatric general physician must always pay due attention.

2. *A physician experienced in physical medicine*. The organization of physiotherapy is the key to the whole problem of geriatric rehabilitation, for physiotherapy must be applied skilfully and with due regard to the patient's physical disability as the most important criterion of bedfastness.

3. *A psychiatrist*. The medical staff of the nearest mental hospital would be a very useful choice, because so many old people now sent to mental hospitals could be adequately cared for and improved physically and mentally in a more helpful environment where emphasis is laid upon the patient's recovery. These patients could then be sent to a long-stay annexe for the mentally confused, or to their own homes without any mention of mental hospitals. So many of these old people with mild senile dementias and cerebral arteriosclerosis need little or no mental treatment at all, but a well-organized kindly discipline with adequate nutrition, some supervision, and gentle occupations. Once again, with so many ambulant patients of this type there is little need for nurses. In view of the impending changes in lunacy certification, if a small proportion of beds were put aside in a geriatric department for this type of case another problem would be ameliorated, while the true senile dementias needing a mental hospital environment would go there after a most sympathetic general medical review of their condition.

4. *A good general surgical service*. This should not be difficult to organize in any area. It is not necessary to emphasize the importance of ophthalmology to the aged.

5. *A urological surgeon* skilled in primary prostatectomy and perineal resection is essential to prevent the drain on hospital beds, nurses' time, and surgeons' time of over-prolonged or permanent suprapubic drainage.

6. *An orthopaedic surgeon* to deal specially with the problem of the fractured upper end of the femur. An active policy of rehabilitation will result in many more patients, whatever their physical or mental condition, being submitted to an operation which, in my experience, produces less shock than being bounced on and off a bedpan several times daily or submitting to frequent changes of bed-linen. Dr. A. J. Lee has shown us that even in the presence of electrocardiographic changes the "immediate" mortality is very small with a well-administered anaesthetic which prevents the possibility of anoxaemia. Incidentally a general anaesthetic given by an experienced anaesthetist is always preferable to a local anaesthetic, for there is less possibility of anoxaemia developing; the shallow respiratory excursion so common in old age may not be sufficient to prevent anoxaemia, especially where a basal anaesthetic is used to supplement the local.

I see no objection to the insertion of a Smith-Petersen pin or applying well-leg traction if by this means a patient's last days are eased and the nurses' work is lessened: sandbag "immobilization" cannot be considered as, in any way satisfactory to patient, surgeon, or nursing staff. Another great waste of nurses' time and hospital beds is treatment of a fractured femur by prolonged traction or Whitman's plaster immobilization for many weeks.

It follows, therefore, that the use of the body as an immobilizing force providing countertraction, in old people at least, must be reconsidered from three points of view. First, there is no doubt that the work of the nursing staff is increased; secondly, the incidence of joint and muscle stiffness is raised, delaying the application of physiotherapy and thereby greatly prolonging its period of application and wasting the physiotherapist's time; thirdly, the method of immobilization increases the incidence of respiratory complications, including pulmonary embolism following phlebotrombosis of the calf and foot veins. Dock (1944) has pointed out that necropsies with complete leg dissections show that 30% of all hospital patients from the age of 17 to 90 have thrombi in the veins of the calf; in adults who have been in bed for two weeks or longer the incidence reaches 60%, while nearly all show necroses and inflammatory reaction in the calf muscles.

### Nursing Staff

Geriatric patients need more nursing and medical attention during the period of active rehabilitation, while as soon as they are ready they can be transferred to a long-stay annexe ward without a nursing service or to a long-stay annexe for bedfast cases. Our depleted nursing service could then be concentrated upon 50 to 60% of the patients, which amounts to almost doubling the available nurses. The active geriatric wards could carry out their routine on a minimal basis of one nurse to four patients, while the 10% permanently bedfast cases would also need at least one to each four patients. It is becoming increasingly obvious that many more nursing orderlies, male and female, will therefore be required.

The correct psychological approach in the acute geriatric ward demands active group rehabilitation, and this is best carried out by the physiotherapist and her orderlies. I have found that the nursing staff cannot accurately assess when an old patient is fit to start rehabilitation or begin getting out of bed; thus the process is slowed. It is wiser, therefore, to hand over the rehabilitation of all physical lesions, either organic or postural, to the physiotherapist and her orderlies as soon as the physician finds no physical reason for further delaying rehabilitation. When more nursing staff trained in this branch of medicine are available this decision can be reviewed. The nursing shortage will be ameliorated by the future interchangeability of district hospital nursing staffs, but for the time being nursing orderlies (three to each ward) will have to be utilized. Indeed, they serve a very useful function in the routine of a ward, performing many non-nursing duties and leaving the nursing staff more time to carry out their work.

It is essential to provide a geriatric service, for a good medical, surgical, and nursing service alone will not help restore old people to activity; only the correct psychological and physiotherapeutic approach can effect this, by affording competitive group and individual rehabilitation, with each patient at a different stage of recovery. As soon as surgical, ophthalmic, orthopaedic, and urological problems have been dealt with the patients should be transferred to the helpful and less hurried atmosphere of the active geriatric ward; for elderly persons obtain no benefit in the noise and bustle of the acute surgical ward, while to see patients 40 to 50 years their junior improving rapidly and going home is to them often nothing but an irritation.

### Premises

Having carried out a geriatric scheme as described in premises by no means ideal, I am satisfied that most public assistance institutions can be utilized temporarily for the provision of the desiderata previously mentioned: active geriatric wards; long-stay annexe wards for patients up part or all day; long-stay annexe wards for the residuum of geriatric bed-fast cases needing constant nursing; and resident homes, which can often be outside the hospital.

The size of the first unit will depend upon the nursing and physiotherapist staff available, but so long as 24 nurses and 12 orderlies, with one or two physiotherapists and four physiotherapist orderlies, can be obtained, it should be possible to run a unit of 100 beds.

We must clearly differentiate between a geriatric service as applied to newly admitted patients and the more difficult and painstaking work of gradually releasing hospital beds and nurses used up in nursing old people who require rehabilitation after years of neglect. It is imperative, however, that the first steps taken should be to solve the more difficult task, as in this way the effects of the nursing shortage can most rapidly be ameliorated. We must be sure that a gradually increasing part of the nurses' time is spent in the active geriatric wards, leaving part-time senior nurses to treat the relatively few permanently bedfast in their long-stay annexe wards. The more this policy is carried out the less will the nursing shortage be felt. It might be expected that an early result of the work of the geriatric departments would be a gradual decrease in the number of beds required. This cannot be the case for some years because of the rapidly increasing number of old people.

### Summary

The view is expressed that improved care of the aged sick must depend upon the organization of a geriatric department in the hospital system.

The medical profession must change its attitude towards these patients from that of resignation to the inevitability of endless months in bed to active investigation, ensuring that each patient has the optimum chance of enjoying even limited activity and independence.

The need for reawakening the nursing staff's interest by the more optimistic approach of the medical profession is stressed.

The importance of physiotherapy in rehabilitating the aged is demonstrated.

Medical staff must consider therapeutic approaches which will economize nurses' time.

The insistence that nurses spend the maximum period of time actively nursing the sick in the active geriatric wards will decrease the unpopularity of this work.

## ROYAL MEDICAL FOUNDATION OF EPSOM COLLEGE

### PENSION, SCHOLARSHIPS, GRANTS

The Council of Epsom College invites applications for a vacant "France" pension of £30 per annum for a necessitous medical man fully 55 years of age who has been registered for five years. Forms of application may be obtained from the Secretary's Office, Epsom College, Surrey.

There are also available: (a) Other pensions for medical practitioners or widows, when vacancies occur; (b) scholarships and grants for children of either sex, not necessarily orphans, but candidates must be of public-school age and in need of such help; (c) grants from the Eastes Trust for the relief of registered members of the profession of any age, their widows and orphans, and educational assistance for their daughters or sons.

## STATEMENT BY THE COUNCIL OF THE BRITISH MEDICAL ASSOCIATION

December 18, 1947

The Negotiating Committee has now completed the work of presenting to the Minister of Health the views of the medical profession on the National Health Service Act, 1946. The Minister of Health has replied to the views of the Negotiating Committee. Every doctor should study carefully both documents, since, as the Minister himself has said:

"Every doctor will have to decide for himself when the proper time comes whether or not he should take part in the new Service, and the profession as a whole will be free to determine their views on the Service when they know what it is to be."

It is now the profession's duty to decide its collective attitude to the Act prior to the making of individual decisions by those doctors affected.

In his reply the Minister acknowledges that the medical profession has worked untiringly for a comprehensive health service to be available to all who need it. The medical profession itself has helped to formulate the plan, a contribution which has too often been ignored by opponents of the profession. The profession objects, not to the aim itself, but to the methods proposed, under the present Minister, to achieve it. It would be useless to disguise that on this subject the differences between the Minister and the profession are deep. On no single major issue has the Minister responded to the reasoned arguments of the profession.

Family doctors entering the Service will be the salaried employees of the State. There is no escaping this conclusion. That the public may not draw from this the deductions which are obvious to most medical men is the tragedy of the present situation. A man can be genuinely responsible only to one master. Until now that master, for the medical profession, has been its patients, to serve whom is its vocation. The need for single-minded devotion of the doctor to those under his care has been for centuries the first lesson to be taught to the young medical student by his teacher. Like other men, the doctor must gain a livelihood. For that livelihood he has been dependent until now on his own skill and his patients' recognition of this. Henceforward for those entering the Service there will be new loyalties and different paymasters—the all-powerful State, whose purposes are not necessarily those of medicine. To-day a doctor's advice is given without fear or favour, and is accepted—within the limits of ordinary human fallibility—as having but one sole object: to help his patient. To-morrow, when the doctor's attention—and loyalty—are divided between his patient and his paymasters in Whitehall (controlled, as these in turn will be, by extraneous considerations of national finance and other non-medical considerations), who knows what conflicts of duty and interest may not occur?

These are not imaginary bogies, conjured up by an alleged "reactionary" profession to impede the progress of "a great social reform." When the Negotiating Committee asked for the abolition of the "basic salary" idea it well knew what it was about.

It is significant that the Minister puts forward no arguments in favour of a universal basic salary. He stated in his letter of Jan. 6, 1947, that the question was still open and that he wished to discuss it with the profession. No such discussion has taken place. Now his arbitrary decision is that every general practitioner must be a salaried officer. The only argument ever used by a member of the Government in support of a universal basic salary is the one used by the Lord Chancellor in the House of Lords when he argued that the salary method was needed for the control of certification. If this is so, the public is vitally concerned. Public safety demands that the individual doctor shall be free to certify what he finds in his patient without fear of Government influence. At the outset the State salary is to be £300 a year. But this figure can be varied by the present Minister or a successor upwards or downwards by simple Regulation and at any time he chooses.

A further safeguard on the independence of medicine disappears with the abolition of goodwill in public general

practice. Nor will any practitioner be able to enter public practice without the ultimate approval of a committee in Whitchall. Do these changes taken together mean that the medical profession must ultimately become the full-time salaried servants of the State? Can they mean anything else? Were they ever intended to mean anything else—bearing in mind the published policy of the party in power?

### Contradictions in Act

This is the central issue, and it is an issue of principle. But since the Act affects every doctor, every doctor will look closely at the terms and conditions to be imposed upon him. Doctors are human, with wives and families of their own to care for. No more than other men can they be expected to appreciate expropriation, injustice, or State-imposed uncertainty about their future. The Negotiating Committee has been advised on high legal authority that certain sections of the Act are contradictory. It is also advised that the Minister's interpretation of these clauses is mistaken in law, and that in any event such ambiguity exists as to render it difficult and dangerous for doctors in partnership to determine whether or not they should enter the Service. These legal arguments have been brought to the attention of the Minister. He has made no attempt to counter them, preferring to say that if he is proved to be wrong in his interpretation he will—presumably if still in power—proceed so to amend the Act as to make his own interpretation legally correct. Meanwhile he leaves it to the individual practitioners to fight out the issues in the courts at their own expense. Needless to say, no amount of retrospective legislation, if such indeed proves eventually to be necessary, can put right the transactions which will have taken place on the false assumption that the Minister's interpretation is correct. Whatever happens, flagrant injustices will have been perpetrated—injustices which could have been averted had the Minister consented to amend these clauses before the Act comes into force instead of afterwards. Here in fact was the crucial test of the genuineness of the Minister's declared intention if convinced by argument to amend the Act. He has declined to amend. Did he ever intend to amend?

In the field of hospital and specialist services the Minister makes some concessions which may or may not survive his tenure of office. Meanwhile they may relieve some of the anxieties of specialists. The main changes are to remove the ceiling of professional fees for a proportion of private beds and to promise not to take over nursing-homes even though they are not conducted for profit. A number of other issues are raised by the documents. For example, there is no evidence in the Minister's reply of any relationship between the proposed remuneration of the general practitioners and the recommendations by the Spens Committee, which he accepted in principle. The profession has repeatedly asked that, before a doctor is dismissed from the Service he should have the right of an appeal to the courts against the Minister's ruling. This right of appeal, which would be a protection for the public as well as for the profession, is still denied.

### Plebiscite of the Profession

The issue now rests with the profession. On Jan. 31 a plebiscite of the whole profession will be taken, and on the results of that plebiscite the British Medical Association will determine its future action. It must be made clear that, whatever the result, no doctor will be advised not to render service to his patients or not to continue with his professional work. If the profession decides against service, consultants and specialists will be advised to continue with their hospital work, meanwhile refraining from entering into contract with regional hospital boards; general practitioners will be advised to continue with their practices but without entering into contract with local executive councils; public health officers will be advised to continue with their work under local authorities. Parliament has given to every doctor the right freely to enter or not to enter the Service. Indeed the Minister, in his reply, draws attention to this right. The medical profession, while never willing to withdraw its service from the public, is fully entitled to say that the State Service offered is, in its considered view, opposed to the best interests of the public and the profession.

The task now before the profession is to strip the non-essentials from the essentials, to distinguish between the shadow and the substance. Despite the Minister's promise that if convinced he would seek amendment of the Act, he has remained unconvinced and impervious to argument; and thus for nearly a year we have worked at the conference table to no purpose.

There remain one final question and one central issue. Does the Service as described by the Minister conflict with the traditions and standards of a great profession? There is only one answer the Council of the Association can give to this question. It does so conflict.

### NATIONAL (WAR) FORMULARY

Amendment No. 1, 1947, of the *National (War) Formulary* (see Aug. 9, p. 225, for other alterations) approved by the N.W.F. Committee is as follows:

- P. 14. *Prokayvit* amended to read "*Prokayvit Oral*."
- P. 15. Entry added:—*Rybarvin (Solution)*: Compound Spray of Adrenaline and Atropine, N.W.F.
- P. 20. *Capsula Pluravit*. Title replaced by *Capsula Vitaminorum (Caps. Vitamin)*. Synonym is retained.
- P. 33. *Linctus Codeini* N.W.F. Title amended to read *Linctus Codeinae* N.W.F.
- P. 34. *Linctus Diamorphini* N.W.F. Title amended to read *Linctus Diamorphinae* N.W.F. "Note" also amended to read *Linctus Diamorphinae* B.P.C.
- P. 34. *Linentum Merhyllis Salicylatis* B.P.C. Formula amended to include: Rape Oil, for alternative use with Arachis Oil and Cotton-seed Oils.
- P. 47. *Mistura Potassii Bromidi et Nucis Vomicae*. The word "to" is inserted in the last line of the formula.

Where medical practitioners continue to order on N.H.I. prescriptions "*Caps. Pluravit*," the chemist is being informed that he shall dispense *Caps. Vitaminorum*. Manufacturers are asked to make immediate arrangements to use the title "*Caps. Vitaminorum*." A title similar to the one originally chosen by the N.W.F. Committee for the N.W.F. multiple vitamin capsule has been granted registration as the trade mark of a particular manufacturer, who, however, is agreeable to the disposal of stocks at present held.

### Preparations and Appliances

#### SELF-CONTROLLED THREE-WAY SYRINGE DEVICE

Dr. DAVID A. HERD (Leeds) writes: I have recently designed and constructed a three-way syringe device which can be completely controlled by one hand, thus allowing the other free to hold the needle in the chest. It consists of a rectangular recess and clamp which holds an ordinary Record 50-ml. syringe; to this is attached a three-way piece from which rubber tubes pass under spring-controlled thumb levers (C., chest; W., waste; D., disinfectant). To facilitate the positioning of the sterile tubes under their respective levers the device can be made to break in half by means of a friction hinge. The piston end is attached by a screw clamp to any suitable fixture, such as the end of a bed or couch. It will be seen that the usual syringe action is reversed.

The advantages of the device are: (1) Syringe and chest needle are entirely under the control of the operator. The patient's chest can be aspirated or washed out at his bedside without assistant or nurse. (2) No special syringe is required. (3) All parts are easily detached for sterilizing or replacing. (4) There are no taps to block or get out of order.

Further information can be obtained from Messrs. Reynolds and Branson, Ltd., Briggate, Leeds, who have now agreed to make the instrument.

## Reports of Societies

### AGGRESSION AND EMOTIONAL DEVELOPMENT

A meeting of the Section of Psychiatry of the Royal Society of Medicine was held on Dec. 9 for a discussion on "Aggression in relation to emotional development, normal and pathological." The chair was taken by Sir DAVID K. HENDERSON. The attendance was so large, including members of the Child Psychiatry Section of the Royal Medico-Psychological Association and the Medical Division of the British Psychological Society, that an adjournment had to be made to a bigger hall.

#### The Contribution of Psycho-analysis

Miss ANNA FREUD spoke of the changes brought about in child psychology by psycho-analysis. These included a re-orientation of the role of instinctive urges in the development of the child. In pre-analytic psychology childhood was regarded as a peaceful period of progressive growth in which the instinctive urges were not a disturbing element, but analytical psychology ascribed to such instincts the main role in the shaping of personality. When the demands made by the environment clashed with the claims of the instinct, the ego had to find a solution. It might choose either to act in submission to environment and opposition to instinct, in which case the child was "obedient" or "good," or to submit to the claims of instinct against the outer world, in which case the child was "naughty." The child was faced with a painful tension within or the threat of injury or punishment from without, a conflict which served as a constant stimulus towards the development of higher function and finally shaped the personality.

Psycho-analytic theory placed the whole of the instinctive urges under two headings: sex and aggression. Infantile sexuality was shown not only to exist but to have perverse manifestations, which made it more difficult of acceptance as a normal, regular, necessary occurrence. The aggressive character of the infantile urges did not escape notice, but it was at first attributed to the cruel nature of infantile sexuality itself. Aggressive outlets were found at an early stage directed against the child itself—as, for example, the head-knocking activities of infants—which were on the verge of abnormal behaviour and might sometimes result in real injury. Biting was another self-destructive activity. It was essential that these aggressive urges should be directed away from the child's own body to outer objects, and at a later age aggression became more normal. It was still self-destructive, but it was vested in the super-ego and directed, not against the body, but against the ego itself.

Thus the factors in child behaviour, Miss Freud continued, included both erotic and aggressive elements. Those who had to do with toddlers knew the exhausting kind of love which they had for their mothers, and which drove some young mothers to the point of despair. Aggressive love threatened to destroy its object. Later the mixture of sex and aggression came to be of a more adult nature; boys at this level dominated but also protected their mothers. They sought to impress and thereby to subdue the loved object. They might fluctuate between being manageable and unmanageable, between the so-called good and bad, but most variations came within the range of the normal. In recent years special interest had been directed towards pathological aggressiveness in young children, mostly orphans or children in broken homes or in institutions. They were not mental defectives, but were uncontrollable, showing either pleasure or complete indifference with regard to the damage they did to things or the suffering they inflicted on persons. The handling of these children was a baffling problem and a challenge to child psychiatry. The pathological factor in these cases was not in the aggressive tendencies themselves but in the lack of fusion between these and other urges. The aggressive urges, not being brought into fusion and thereby partially neutralized, remained free and were manifested in cruel independent destructiveness. Appropriate therapy would be directed to the emotional development with a view to securing this fusion.

#### Instinctive Behaviour

Dr. CLIFFORD SCOTT, who paid a tribute to Sigismund and Anna Freud for the new understanding they had brought to child psychology, said that in the early weeks of an infant's life it was not easy to separate the drives, wishes, and instinctive attitudes and study them in isolation; nevertheless, they were on sure ground biologically when they thought of instinctive urges as leading to consciousness in the form of desire, appetite, and hunger, and, in a suitable situation, to satisfaction. They were less sure of the point at which the line leading to satisfaction was altered and the new attitude of aggression became manifest. From clinical observation of both children and adults, especially mentally affected children and psychotic adults, there was much evidence that instinctive behaviour became more and more energetic until finally, if satisfaction did not occur, disorganization began. It was necessary to distinguish between two happenings in early life—that which led to satisfaction, and that which led to frustration and the development of aggression. Once aggression had occurred it was remembered, repented, developed, and exploited, and its repetition involved associated fantasy. At any stage of development it was as important to assess the nature of aggression as it was to assess the type of sexual development. Inhibited aggression in the presence of inevitable frustration presented a most difficult problem. It was one of the most important pointers in childhood to the possibility of psychosis in later life. Exaggerated aggression was another problem to which much of the psycho-analysis done in this country during the last twenty years had provided some answer. There was a splitting of the ego in such a way that the loving and the aggressive aspects were kept widely separate, thereby preventing normal development. It was necessary to strike a balance between the destructive use of aggression and the opposing use of love before behaviour could be rightly discussed in terms of normal and abnormal.

Dr. D. W. WINNICOTT said that in aggressive children any one act of aggression must involve the whole child; no aggressive act could be treated as an isolated phenomenon, and the child must be considered in his environment and in his relation to adults. It must be remembered also that even the maturing child contained within himself various degrees of immaturity. The child must be considered as a person having fixations at immature levels, also as in a labile emotional state, liable to be aggressive and to recover therefrom given a suitable environment. Prior to the integration of personality there was non-purposive aggression. The baby kicked in the womb, but it could not be assumed that it wanted to kick its way out. The infant chewed the nipple with its gums, but it could not be assumed that it wanted to hurt. The integration of personality did not arise at one particular point; it came and went, and with it there arose purposive behaviour. From then onwards the child who was aggressive meant to be aggressive.

Dr. Winnicott traced the emotional development of the child up to the emergence of a feeling of guilt as the result of his aggression, the guilt referring to the damage he had done to the loved person. In this way much aggression was transferred to a social function. Frustration acted as a seduction away from guilt towards the defence mechanism; there was an easing of guilt, but love lost some of its valuable aggressive components. It was important to study the complex series of defence mechanisms in any attempt to understand the child who had reached this stage of emotional development. In health the child's interests were directed both towards external realities and towards his inner world, but in ill-health the relationship might be reorientated, so that the "good" was concentrated within and the "bad" was projected; thus the child became pathologically introverted, and at such a point regularly became aggressive. Many children continued to live in their inner world, as indeed did many adults, never achieving a capacity for objectivity. The inner world to the child was localized primarily in the belly, and secondarily in the head or some other specific part of the body. If the child who had reached some power of organization had experience of, for example, quarrelling between his parents, the quarrel, so to speak, continued to live inside him, and a certain amount of energy was directed towards attempting to control the internal

bad relationship. When the internal bad relationship took over he developed aggression like the quarrelling parents themselves. Clinically there appeared a dramatization of badness, manifested by kicking, passage of flatus, and the like, or alternatively a kind of suicidal attempt, aimed at destroying the bad within the self. In the more mature child the story was the same, but the accent was on genital rather than oral experiences. To ensure maturity stable conditions of environment were essential.

### Frustration Theory of Aggression

Dr. JOHN BOWLBY said that the persons to whom the small child exhibited the greatest aggressiveness were the members of his family, for whom he had also a feeling of affection and on whom he was dependent. Hatred of loved persons predisposed the child to the development of mutually antagonistic systems within himself, with consequent self-hatred and self-damage characteristic of the instability of the neurotic person. A study based on the observations of parents showed that angry outbursts were most frequent during the second year of life. As the child got older the outbursts were fewer and more purposive. Poor health and hunger predisposed the child to outbursts, and increased aggression, overt or repressed, could be traced to a number of emotional situations of a frustrating kind occurring during the first three or four years of life and brought about by an autocratic discipline or an over-protectiveness on the part of the mother, or by the separation of the small child from the mother, which gave him a feeling of insecurity. It was only in situations such as these, when the child's relationship to his parents had been badly affected, that pathological sequelae appeared. An objection to the frustration theory was that certain children were sent into paroxysms of rage at minor frustrations which other children took in their stride, but when these cases were investigated the frustration theory was confirmed, for the child who reacted to minor frustrations with rage was the child who had already undergone a major frustration. The experience of an increasing number of children's psychologists was that the child whose primary need for good relations with his mother had been frustrated was the child who reacted to pin-pricks with disproportionate outbursts. It might be that genetic factors enabled some children to tolerate frustration more easily than others, but genetic factors should not be invoked too easily to explain aggressiveness.

Any proposal to bring up children without frustrating them was manifest nonsense, but on the extent to which it was possible to reduce frustration depended in a great measure the prevention of mental illness and instability. Studies should be carried out by workers analytically trained in the study of human relationships. Children would develop favourably and without undue aggression if in their early years they were continually with parents who wanted and enjoyed them, and who were able to develop a give-and-take relationship, neither insisting on autocracy nor making doormats of themselves. This was not to prescribe the impossible. Despite the mistaken teaching of many doctors, some educationists, and even a few psycho-analysts, many children were already brought up in this way.

In some general discussion Dr. MELANIE KLEIN expressed surprise that the question of heredity had not entered into the discussion. She could not agree that thumb-sucking was an attribute only of the abnormal child; it was instinctive in the search for comfort. Dr. STENGEL said that Freud's dualistic theory, especially the concept of the fusion of the erotic and aggressive impulses, had been of great help to him as a general psychiatrist in attempting to understand the reactions of the child. Dr. FELIX BROWN mentioned the importance of the factor of sibling jealousy in the development of aggressiveness.

### Criticisms

Sir DAVID HENDERSON, from the chair, in closing the discussion, said that he thought that Miss Freud had given a too optimistic picture. She had suggested that with the fusion of the erotic and aggressive instincts, accomplished almost automatically, good behaviour would result. He found this a little difficult to grasp, and he wondered how far this theoretical

conception had been proved in practice. With regard to Dr. Scott's contribution, he himself could not differentiate, as apparently Dr. Scott did, between hate and aggressive love. Where did love cease and aggression become the paramount factor? As for Dr. Winnicott's theory, he thought it would be difficult to establish before a judge in court or a board of medical assessors. It did not seem right to have theoretical concepts without actual facts being given in support of them, at least facts on which dogmatic statements could be made. Dr. Bowlby, he thought, had not paid enough attention to genetical constitutional factors, though every practical psychiatrist would weigh up the environmental situation before accepting a genetical explanation.

The trouble with such a discussion was that too much was attempted, and owing to shortness of time no speaker had been able to develop his very complicated theme.

The openers briefly replied.

### PENICILLIN IN ACUTE OTTIS MEDIA

At a meeting of the Section of Otolaryngology of the Royal Society of Medicine on Dec. 5, under the presidency of Mr. DONALD WATSON, the subject of penicillin treatment in acute suppurative otitis media was discussed.

Dr. A. YOUNG presented a study of a series of cases in Mr. Simson Hall's department of the Edinburgh Royal Infirmary. The number of cases, extending over the period from early 1946 to June, 1947, was 115. All cases with a previous history of deafness or discharge were excluded, also all cases which on admission appeared to require immediate mastoid operation, all cases of children under 5, and all cases with a history of over one month's duration. The fact that a patient had been given a sulphonamide before being referred to the department had to be disregarded. Penicillin was given by intramuscular injection in doses of 200,000 units daily for in-patients, with three-hourly injections of 25,000 units, and in doses of 100,000 units twice daily for out-patients. As time went on and penicillin became more easily available and less costly, larger total doses were given; the average was 1,300,000 units, equivalent to just over six days' treatment, and the maximum was 2,500,000 units. Oily preparations of penicillin were tried in the case of out-patients, but they complained of pain and discomfort and preferred the lesser inconvenience of more frequent attendances.

Of the 115 cases 10 were bilateral. The drum was perforated and discharge was present in 56 and the drum was bulging in 44 cases. In cases of perforation and discharge x-ray examination of the mastoid at the start of treatment showed some degree of opacity. The commonest organisms found on culture were haemolytic streptococci, and less often staphylococci. In no case was a penicillin-resistant organism encountered. Paracentesis was performed in only 8 cases, and there was no evidence to show that the cases in which it was not done suffered any impairment of function which might have been avoided.

A dry ear followed penicillin treatment alone in all but 6 cases; in 6 cases a simple mastoid operation was necessary, and one required in addition removal of adenoids. In 10 cases there was recurrence of infection; in 2, more than one recurrence. In one case signs of meningitis accompanied the recurrence. The simple mastoid operation was done in two of these cases before final healing. The time taken for the ear to become dry averaged 7-8 days, and the time for the drum to return to normal and for normal hearing of the whispered voice to be recovered was 11 days in the cases in which suppuration had been present and 9 days in the cases in which it had not. Comparable figures for cases treated with sulphonamides were 9 days for the ear to become dry, and 17 days for the drum to return to normal if suppuration had been present, and 14 days if it had not.

In 8 of the cases there remained some defect in hearing. In only one was this at all marked; in the other 7 it could be described as slight. Hearing tests were repeated at intervals until it appeared that no further improvement was to be expected. In some cases satisfactory audiograms were obtained

in two or three weeks; in others it was necessary to follow up the cases for months. The hearing levels for each frequency were averaged out, and showed for the different ranges an average comparative loss of hearing of from less than 5 up to 10 decibels. At 256 frequency, for example, the average loss was 2.5 decibels, made up of 59 cases with no comparative loss of hearing, 20 with a comparative loss of 5 decibels, and 13 with a loss of 10 or more. At the beginning of the investigation alternate cases were treated with sulphonamides, but after a time this was given up. The average audiograms for the cases treated with sulphonamides showed remarkably little difference from those treated with penicillin, but, of course, the number of cases was smaller. The results of penicillin treatment in recovery of function for all practical purposes might be considered remarkably good.

#### The Reason for the Investigation

Mr. I. SIMSON HALL said that the public was demanding penicillin on the slightest provocation, and the wave of enthusiasm which greeted its introduction made it all too easy to assume that here was the answer to the otologist's prayer. It seemed that although in the severer complications of otitis media it was undoubtedly a wonderful addition to their armament, yet in the treatment of the slighter and earlier forms of otitis there was much still to be learned. The neurosurgeons declared that penicillin failed to penetrate into an intracranial abscess so long as there was tension within that abscess. There was considerable tension in the middle ear, and if there was no penetration of the drug into the middle-ear cavity obviously paracentesis would be an essential preliminary where there was an acutely bulging drum. A patient was given 250,000 units of penicillin and twenty minutes later a paracentesis was done. Before doing the paracentesis the contents of the middle ear were aspirated and submitted to a bacteriologist with a view to discovering whether there was penicillin or the products of penicillin within the affected fluid. The bacteriologist reported that there was a satisfactory degree of bacteriostasis in the middle-ear fluid, which was assumed to mean that penicillin had in fact penetrated the middle-ear cavity. More work on this point needed to be done.

With regard to the final results of treatment, the residual hearing defect in a number of cases was not great, but it remained to be seen what happened to these people in ten or more years' time. Eighteen to twenty months' observation was far too short. Within the last month 22 patients had been seen in whose cases previous x-ray records were available. Examination of the films together with the audiometric records seemed to show that although there was a degree of mastoid involvement it was not of any special significance; 11 of the 22 now had normal hearing and 11 some impairment.

The advantage of penicillin over the sulphonamides seemed to be that patients returned to normal some 4 or 5 days earlier; but penicillin treatment must be given regularly, and the general impression was that four-hourly treatment was the ideal. It was difficult to imagine a busy general practitioner carrying out penicillin treatment four-hourly, and it was something of a relief to find that sulphonamide treatment, so far as late results were concerned, seemed to hold its own in the field. Therefore his feeling was that in general domiciliary practice reliance should be placed chiefly on the sulphonamides.

#### Penicillin-resistant Strains

Within the last week, Mr. Simson Hall added, there had been published a paper<sup>1</sup> showing an analysis of *Staph. pyogenes* infections and indicating that the proportion of penicillin-resistant cases had risen from 12.5 to 38% in a year. It might be inferred that in a matter of months penicillin as a means of treatment in staphylococcal infections would be a back number. Happily, the same proportion did not obtain with streptococcal strains, but the percentage of streptococcal strains which were penicillin-resistant was increasing. One of the chief reasons advanced for penicillin resistance was inefficient administration. As a major factor in the production of autogenous

intracranial disease the streptococcus seemed to be on the way out and the staphylococcus and others on the way in, and in future it was likely that these infections would be encountered with increasing frequency.

He had been asked what he considered to be the proper dosage of penicillin. He had no certain knowledge. The enormous doses which had been fashionable in some places were very attractive in theory, but he doubted whether they were on a substantial basis. Finally, he reaffirmed his view that these valuable drugs were an adjunct to surgery, not an alternative, and said again that his remarks applied to early acute otitis media only.

#### General Discussion

A large number of speakers took part in the general discussion. Mr. T. B. LAYTON put it forcibly that the appearance of a case of chronic otitis media was a sign of failure on the part of the parents, the general practitioner, or the surgeon. Mr. E. G. COLLINS said that penicillin treatment disturbed the bacteriological balance when a mixed infection was present, and under the local application of penicillin or the use of penicillin lozenges *B. proteus* and the coliform organism took on a greater activity. Mr. J. H. OTTY opposed Mr. Simson Hall's suggestion that where penicillin could not be given efficiently sulphonamide drugs should be used; he was afraid of their masking effects. Mr. W. A. MILL, on the contrary, doubted whether masking was a real danger if proper precautions were taken. Mr. L. GRAHAM BROWN said that masking was a real thing, but it did not occur so much now because practitioners were aware of the danger.

Mr. G. EWART MARTIN supported Mr. Simson Hall's assertion that the sulphonamides and penicillin were adjuncts; they should not be regarded as the only treatment. It was necessary to get back to the education of the otologist on normal lines, not with penicillin in the background the whole time. Mr. R. SCOTT STEVENSON raised the question of Eustachian catheterization. Mr. GAVIN YOUNG said that formerly cases of acute mastoiditis were met with once or twice a year; now, as a result of inadequate chemotherapy, the number had multiplied. Mr. F. C. W. CAPPS would like to have seen, alongside the cases presented by the openers, a series which had been treated on the old orthodox lines by drainage. Mr. R. L. FLETT said that a good deal turned upon the appearance of the tympanic membrane. Mr. H. V. FORSTER pleaded for the treatment of cases of otitis media in hospital so far as possible. Mr. P. SCOTT referred to the danger of masking, especially with penicillin tablets given for use at home. Mr. A. MACKENZIE ROSS said that any child with acute earache should be under the supervision of an otologist. The PRESIDENT (Mr. Donald Watson) said that the ultimate hearing depended on the amount of scar tissue in the ear, whether penicillin was used or not, and whether otosclerosis would follow these treatments in a few years' time was an open question.

Mr. SIMSON HALL, in reply, said that he had not been able to arrive at any rational explanation of the high-tone loss which had occurred in many of these patients. With regard to masking, he thought that this occurred with penicillin just as often as with sulphonamides. These were agents which they were not taught as students to use; they had had to learn their use for themselves, and they had still to learn the danger signs.

#### METALLIC CONTAMINANTS IN FOODSTUFFS

The Food Group of the Society of Chemical Industry held a joint meeting with the Society of Public Analysts on Dec. 3 for a discussion on the occurrence, physiological importance, and estimation of metallic contaminants in foodstuffs.

Mr. G. E. FORSTNER said that metals or trace elements should be regarded as contaminants only when present in such amounts that the safety limit for the health of the consumer was transgressed. A trace element had been defined as one that was widely distributed but rarely exceeded 20 parts in a million in the food consumed. The limit for arsenic fixed by the Royal Commission in the early part of this century—the Commission set up following an outbreak of poisoning due to arsenic in beer—was 4 parts. The importance of natural

A&amp;H

**I**ncreased capillary fragility with its attendant risk of submucous or subcutaneous hæmorrhage, is the primary indication for the therapeutic use of Rutin, a flavonol glycoside credited with the physiological properties hitherto ascribed to vitamin P.

Clinical trials, some of which were summarised in the *British Medical Journal*, May 31st, 1947, page 771 suggest that Rutin may be an important factor in the prevention of retinal hæmorrhage in patients with hypertension, and in controlling bleeding in hereditary telangiectasia.

Rutin A&H is suggested for administration in hæmorrhagic conditions due to increased capillary fragility associated with hypertension, diabetes, nutritional deficiency or toxic effects of drugs.

Rutin Tablets, each containing 20 mg. are available in bottles of 100

## RUTIN A & H

Literature and price on application.

Price £45

PERIHEL LIMITED (Dept. D.M.J.1)  
17-19, EDGE STREET, LONDON. W.8

*For Normal Infant Feeding*

BIRTH TO NINE MONTHS

## Humanised Trufood

### PROTEIN

The ratio of casein to lactalbumen is adjusted to provide a total amino acid content which closely resembles that of human milk.

### FAT

The presentation of the fat in the form of a finely diffused emulsion reduces the likelihood of fat intolerance.

### CARBOHYDRATE

Lactose is the only carbohydrate present and constitutes 50/55 % of the total solids.

### 1 OZ. OF POWDER CONTAINS:

600 I.U. Vitamin "A"	150 mg. Calcium
320 I.U. Vitamin "D"	150 mg. Phosphorus
	0.3 mg. Iron

**HUMANISED TRUFOOD.** An infant food scientifically balanced to the standard of Human Milk.

Further details supplied on request to:

TRUFOOD LIMITED (Dept. BM22)  
Bebington, Wirral, Cheshire

TF 246MA/7

# Potatoes & Vitamin C Intake

Vitamin C provided by total rationed foods including potatoes compared with the accepted requirements.

"A question that needs immediate attention is whether the time has now come for the general issue of ascorbic acid tablets . . ."

(*The Lancet*, Nov. 15, 1947, p. 730).

Since the potato is regarded as an important source of vitamin C, the restricted weekly ration of 3 lb. for one normal consumer means a greatly reduced intake, not easily made good during the winter months by alternative vegetables and fruits.

Ample supplies of 'Redoxon' Vitamin C tablets are available at economical rates.

## 'REDOXON' VITAMIN C

Tablets: 50 mg., 25 mg. and 5 mg.

Ampoules: 2 c.c. (100 mg.) and 5 c.c. (500 mg.)

Samples and further information on request.

**ROCHE PRODUCTS LIMITED**  
WELWYN GARDEN CITY, HERTS

Scottish Depot: 665 Great Western Road, Glasgow, W.2

# 1912 'LUMINAL' 1948

Decades of intensive use in therapy have served only to emphasize the wide importance of the combination of sedative, antispasmodic and hypnotic properties that is 'Luminal.'

With suitable adjustment of the dosage 'Luminal' is effective in over twenty indications. Amongst the more important are: epilepsy, hysteria, migraine, chorea, insomnia, pertussis, pruritus, and vomiting of pregnancy.

'Luminal' is a Registered Trade Mark.  
'Luminal' and 'Luminal' Sodium are available as Powder, Tablets and Ampoules. Literature on request.

BAYER PRODUCTS LTD., AFRICA HOUSE, W.C.2

4711

## Priority Groups

It is well known that inadequate feeding and shortage of vitamins in the diet may result in irreparable damage to the pregnant woman and the growing child. In these days of austerity, therefore, expectant and nursing mothers and children are recognised as priority groups, especially where their nutritional needs are concerned.

Marmite supplies essential vitamins of the B<sub>2</sub> complex and, in addition, it contains a useful anti-anæmic factor of particular value in nutritional macrocytic anæmia. It is prescribed extensively in maternity and child welfare work and in private and hospital practice.

## MARMITE

yeast extract

contains

Riboflavin (vitamin B<sub>2</sub>) 1.5-mg. per oz.

Niacin (nicotinic acid) 16.5 mg. per oz.

Jars: 1-oz. 8d., 2-oz. 1/1, 4-oz. 2/-, 8-oz. 3/3, 16-oz. 5/9

Obtainable from Chemists and Grocers

Special terms for packs for hospitals, welfare centres and schools

arsenic in food was not at that time appreciated; not until 1926 was it recognized that the limits for other foods could not apply to certain fish. Dried herbs, especially parsley, had been found to contain arsenic up to 8 parts in a million. The general situation concerning arsenic was quite satisfactory.

Lead, a cumulative poison, was in a different category. Sea crustaceans had a natural lead content of some 7 parts in a million. Sardines also contained lead, and a limit of 5 parts in a million was fixed for imported sardines. Beer and cider might contain lead, and so might tea and desiccated cocoa, owing to the lead linings of the chests. Up to the last year or two curry powder with 50 parts of lead had been found and from 10 to 20 parts were not infrequent. An undue proportion of samples of corned beef had been found in recent years to contain lead; of 218 samples, 4 contained more than 100 parts in a million, and 7 between 50 and 100 parts.

Before the war port medical officers of health fixed a limit for copper in tomato products of 100 parts in a million. Published work showed that the natural content of copper in tomatoes was 35 to 40 parts. Copper was an invariable micro-constituent in marine invertebrates and in calf's liver and other foods, and was regarded as an essential nutritional element for which it was difficult to fix limits: A limit of 30 parts would meet most cases; a figure higher than this argued careless preparation and should give rise to suspicion. The same was true of anything above 100 parts of zinc, which was not an important contaminant. The only metal other than arsenic for which a limit had been fixed by official recommendation was tin, which was found mostly in canned foods such as loganberries and acid fruits, but with the use of lacquered cans tin contamination was very small. Carrots sometimes had a high tin content. In Gruyère cheese wrapped in tinfoil as much as 600 parts of tin in a million had been found. Of other metals, cadmium was responsible for a food-poisoning outbreak among 60 airmen in New Zealand in 1944, due to food stored in cadmium-plated vessels. Selenium was a problem in certain parts of the United States owing to some property of the soil; it caused a vague illness. The speaker pointed out the difference between pre-war and present conditions. Formerly there was no hesitation in sacrificing consignments of food on suspicion, but now food had to be conserved as much as possible.

#### Public Health Aspect

Mr. G. W. MONIER-WILLIAMS, Ph.D., F.R.I.C., said that arsenic and lead were in a class apart because of their toxicity in small amounts; copper, zinc, and tin were responsible for chronic as distinct from acute poisoning. The limits of arsenic content recommended by the Royal Commission had never been given statutory force, but they were generally accepted as standards. They might be criticized as too severe, but the Commission's view was that the presence of arsenic in food was purely adventitious, and that in good commercial practice the arsenic content could be kept below the specified limit. The later discovery that sea-fish contained relatively large amounts did not alter these requirements, for while arsenic in fish could hardly be said to be natural, it appeared to be comparatively non-toxic.

Lead was almost as toxic as arsenic, and was a good example of a cumulative poison. It was stored in the body, especially in the bones, and in certain circumstances could be liberated again into the blood stream and might give rise to symptoms of poisoning long after the actual ingestion of the lead. Lead was more easily absorbed from liquid than from solid food. An average daily intake of 2.5 mg. in cider could cause lead colic. Instances of lead colic following the eating of sardines were on record. With a high-calcium diet lead absorption was low, and with low-calcium diets it was high. The normal amount of lead ingested in food and water and inhaled dust was said to be 0.4 mg. a day. It was possible that much of the lead which appeared in the faeces had been absorbed by the liver or into the general circulation, and afterwards excreted. It was widely held that the maximum limit of lead in domestic water supplies was 0.5 part in a million. A limit should be set to the total intake of lead from all sources at 1.0 or 1.25 mg. daily, and tolerance for different foods calculated on that basis. Some authorities considered that a daily intake of 1.0 mg. might

eventually prove toxic and be responsible for nervous symptoms and conditions of slight ill-health. Women were more susceptible to lead than men, but workers in lead industries seemed to be able to ingest large amounts without symptoms. A statutory limit for lead in food was long overdue. It should represent the highest standard reasonably to be expected from manufacturers and distributors. With all the knowledge there was about the toxic action of lead it was remarkable that, with two or three small exceptions, no specific regulations or even agreed limits were in force, nor was there any control over lead pipes, glazes, enamels, or lead solder in food packing.

Acute poisoning from copper and zinc in food had occurred on several occasions, but there were practically no records of chronic poisoning due to the continued ingestion of small quantities. There was evidence that these metals were in fact absorbed and carried to the liver by the portal blood, and from the liver returned to the intestine by way of the bile duct. It was not easy to determine how much passed through the alimentary tract unabsorbed and how much was absorbed and subsequently returned to the intestine. Was the passage of these metals through the liver and their possible retention in the liver without significance? It must be assumed that in some cases the liver was less efficient than in others. A strong argument for the control of copper in foods lay in its effect on oxidation, particularly on the oxidation of ascorbic acid. What was the "doubtful" range of copper? The normal intake from food was 2.0 to 2.5 mg. daily, but this might be considerably higher if the diet contained liver, nuts, etc. The view might be taken that extraneous copper, zinc, and tin were in general undesirable and unnecessary and should be kept to the lowest limit by a scheme of standards with a fairly wide margin for contingencies; but the allowable might tend to become the normal, and an increase rather than a reduction of daily intake result. Public health might be better served by dealing promptly with the grosser forms of contamination, particular attention being given to liquids.

#### Trace Metals in Nutrition

Mr. W. F. J. CUTHBERTSON said that cobalt and copper had been shown to be essential for the nutrition of ruminants, and copper, manganese, and zinc for such animals as the rat. The function of cobalt and manganese was that of an enzyme activator; the function of copper was the synthesis of haemoglobin and cytochrome oxidase, and of zinc that of carbonic anhydrase. In human nutrition the amount of copper requisite for adults had been stated tentatively at 2.0 to 2.5 mg. a day, of manganese 4 mg. a day, and of zinc 12 mg.; and in the case of children, of copper 0.1 mg. per kg. of body weight per day, and of manganese and zinc 0.2 to 0.3 mg. Copper deficiency in the human adult had never been satisfactorily described, but in the infant it had been shown that copper deficiency could result in a type of anaemia which was resistant to iron but cleared up with the addition of copper to iron. In the rat and mouse the characteristic symptoms of manganese deficiency were derangement of sexual function and interference with ovulation ending in sterility in both sexes; in the chick there was an abnormality in bone growth. Human beings probably require manganese, although no deficiency disease attributable to manganese lack had been described. The required amounts of manganese, which was particularly associated with cereals, were assured in the meanest diet. Symptoms of zinc deficiency in the rat and mouse were failure of growth and particularly loss of hair. Here again it was deduced that zinc was essential in human nutrition. In spite of the fact that no deficiencies had been recorded. It was considered that zinc might have some part to play in insulin metabolism.

Mr. N. L. ALLFORT and Mr. D. E. GARRATT described the various techniques employed in the estimation of metallic contaminants, and the latter pointed out that the introduction of statutory limits had its drawbacks. With arsenic and lead which were cumulative poisons, the aim should be complete elimination. The use of an inflexible standard for arsenic, such as 1.4 parts in a million, was unimaginative. Discretion might be used and tolerances allowed with food adjuncts which were consumed only in small quantities; but here again, while synthetic substances introduced into food might at first be in

small proportions, the proportion might grow larger. Copper and zinc were necessary for human needs and were not cumulative poisons. The tolerance limits, until further physiological information was available, should be those necessary to prevent gross contamination of food products. He suggested that the first steps towards laying down desirable limits for different foods should be in the form of a schedule prepared by the Society of Public Analysts to which analysts and commercial firms might be expected to conform. Mr. A. C. BACHARACH gave examples of the difficulties of laboratory experiments, and suggested that changes in dietary pattern needed to be watched with great care. One of the things which should be attended to in diet in addition to caloric intake, vitamin intake, protein intake, etc., was the question of trace metals. It was easy to put too much in, but easy also to take too much out.

### PROGNOSIS OF MENTAL DISORDERS

At a meeting of the Manchester Medical Society on Nov. 5, Dr. G. HOWARD KITCHING said that mental disorders fell into four principal groups. A reduction of cerebral capacity if congenital represented mental defect; if acquired it constituted one of the forms of organic dementia. Confusional states might be included in this group. The prognosis of mental defect was, of course, hopeless. In the organic dementias the ultimate tendency was downhill but often with surprisingly long remissions, especially if the onset was acute and associated with some toxic cause.

Reduction of co-ordination included all those diverse conditions which had as a fundamental feature a discrepancy between thinking and feeling—the schizophrenic-paranoid series of illnesses. In general the prognosis of this group of disorders was bad. Cases with an acute onset had better prospects than those of insidious onset, and the prognosis was much affected by the duration of the condition. Obsessional disorders might also be included under this heading.

Reduction of control was found in the group in which affective disorders or disturbances of feeling showed themselves by excessive elation, depression, or anxiety. The response of affective disorders in general to E.C.T. was specific and dramatic; it cured many of the minor cases as well as most of the major ones.

The fourth group included the psychoneuroses, hysteria, and anxiety hysteria, in all of which the provoking situation appeared to be a predominant factor. A strong element of constitutional predisposition had to be postulated in these patients because the situations which provoked these disorders were common to all people, whereas the neurotic reactions were not.

Prognosis might be considered collectively or individually. The number of people certified annually in any community was an index of its activity in mental hygiene. Psychiatric social workers and a vigorous interest in mental hygiene increased the number of certified cases by facilitating their direction to the appropriate hospitals. In England the figure was 5 per 1,000. In any community the amount of serious crime varied inversely as the number of people certified, and one mental hospital bed was roughly the equivalent of one prison bed. Discharge rates were completely fallacious. The average length of stay in an institution was more than ten years, or one-sixth of the duration of life, which meant that in an average lifetime one person in 33 was certified at some time or another. Statistics tended to show that a psychosis was essentially a chronic and relapsing illness, analogous in medicine to gout, allergy, psoriasis, and diabetes. Considered statistically, the value of new therapeutic procedures, such as insulin for schizophrenia, was problematical.

### Recent Advances

The individual prognosis in cases of affective disorder had been completely altered by electro-convulsion therapy. The prognosis in cases of involutional depression untreated was that one-third got well, one-third remained stationary, and one-third went downhill. With E.C.T. one might confidently expect a recovery rate of 80% or over. E.C.T. was almost equally

valuable in states of elation, which were much less common than depressive states, but it appeared to have little value in schizophrenia or in other psychoses. For schizophrenia the majority of workers favoured insulin shock therapy, which reduced the duration of the patient's stay in hospital and gave a higher proportion of remissions in acute cases. Such improvements were often not maintained and the long-term results tended to approximate to those of the untreated disorder.

Prefrontal leucotomy had also altered the prognosis of mental disorder. The results were difficult to assess because, as it produced irreversible changes, the operation was not tried in early cases until other methods had failed. It cured many depressive and agitated states which had failed to respond to E.C.T., had been followed by good results in schizophrenia, and in many cases changed a socially unacceptable into a socially acceptable psychosis.

At a meeting of the Devon and Exeter Medico-Chirurgical Society on Nov. 20 Mr. W. J. BISHOP discussed some of the notable medical figures of the South-west during the past three centuries. Starting with Robert Vilvain, of Exeter, who published a book of epigrams in 1654, Mr. Bishop talked of Richard Spicer, Antony Salter, and Sir Simon Baskerville the Rich, who was buried in St. Paul's. He mentioned John Attwell, who obtained spectacular cures by prescribing milk and apples, was renowned for piety and benevolence, and lived to a great age. John Bidgood was "haughty and repulsive," and, though professing the motto "Use all men ill," rendered to his patients every possible attention. In *Lancelot Greaves* Smollett immortalized the early career first as a surgeon's apprentice and then as a naval surgeon of James Yonge, of Plymouth. In later life he was made a member of Surgeons' Hall without examination—a signal honour; became a Fellow of the Royal College of Physicians, having first been assured that the "catechizing should be plain and the fees low"; and in 1702 was admitted to the Fellowship of the Royal Society.

Mr. Bishop noted the close association between the physicians of Exeter and Exeter College, Oxford. Other Oxford colleges, however, educated some of these physicians, notably William Musgrave, who was first an undergraduate and later a Fellow of New College. John Blackall and "the able, amiable, and humane" Hugh Downman were Balliol men. The celebrated Sir George Baker, who discovered the cause of Devonshire colic, was educated at Eton and King's College, Cambridge. Other famous or notorious characters touched upon were John Huxham, James Parsons, John Shebbeare, Thomas Glass, John Mudge, John Wolcot, John Sheldon (the amateur balloonist), Bartholomew Parr, John Cunningham Saunders, Thomas Slapton, and the Budds of North Tawton.

At a meeting of the Liverpool Medical Institution on Nov. 27, with the president, Dr. H. WALLACE-JONES, in the chair, Dr. LENNOX JOHNSTON read a note on the cure of tobacco smoking. Dr. Johnston said that, owing to the imposition by tobacco addicts of a powerful "drug taboo," adequate knowledge of the facts about smoking was as difficult to acquire to-day as was an adequate knowledge of sex at the beginning of the century when the sex taboo was at its height. Mr. F. E. STOCK described a new incision for thoraco-lumbar splanchnicectomy, which began just behind the posterior axillary line and passed downwards to a point just in front of the anterior superior spine. Finally, Dr. JOHN A. ROSS discussed stereoscopic screening and described in detail Weigelt's method applied to x-ray screening.

On Dec. 1 the Ministry of Health took over from the Ministry of Supply general responsibility for purchasing medical supplies to meet Government requirements. This transfer is in conformity with the general policy of handing over various wartime functions of the Ministry of Supply to the appropriate Government Department. The change over was effected under the Transfer of Functions (Medical Supplies) Order, 1947, which was published on Nov. 21. It involved the transfer to the Ministry of Health of the functions, responsibilities and staff of the Directorate of Medical Supplies, including those of the Penicillin Production Control and the related Contracts Branch of the Ministry of Supply. All correspondence, which was formerly addressed to the Directorate of Medical Supplies, should from Dec. 1 be addressed to the Secretary, Ministry of Health, Whitehall, London, S.W.1. The telephone number (Abbey 7738) remains unchanged, but the new telegraphic address is "Localise, Parl, London."

# Correspondence

## Censorship

SIR,—Under any form of Ministry of Health administration in which medical practitioners become State servants a situation may arise similar to that now obtaining in the Ministry of Education. Here no official is permitted to write educational books unless express permission has been given; and even when this is granted the Ministry have claimed the royalties earned, on the grounds that the authors are full-time officials.

In medicine such a situation would be disastrous, for articles or books criticizing official lines of treatment might be frowned upon, held up, or even suppressed. We see this form of censorship in communications from officers in the Services, where permission has still to be obtained from higher authorities even now when the need for secrecy is no longer an excuse. The whole idea of such a censorship in civil life is inimical to freedom of thought. We do not want to see any such restriction in the expression of opinion in scientific medicine. It is to be hoped therefore that these fears will be borne in mind by the Negotiating Committee, and a definite statement obtained that there shall be no attempt to restrict expression of opinion in medical literature, and that the labourer shall obtain the full reward of his labour even though he be a whole-time official.—I am, etc.,

London, W.1.

J. JOHNSTON ABRAHAM.

## The Extent of Neurosis

SIR,—Dr. T. J. Burke's reply (Dec. 6, p. 929) admirably expresses a prevalent attitude of the G.P. to the functionally ill. But who can be so expert at helping neurotics as the seasoned G.P.? Handicapped by lack of time set aside for psychotherapy he yet achieves much by sympathy and advice based on his understanding of his patients and their circumstances. He is the front-line fighter against disease, perpetually up against the problems that harass mankind. Who are the back-room boys who can do so much more for his neurotic patients than he can, given time?

Dr. Burke hopes that more psychiatric clinics will be set up in the near future. I hope that those clinics will be set up and staffed mainly by G.P.s like Dr. Burke, each attending for two three-hour sessions weekly. So I would ask him to agree that family doctors who are family men are better qualified to treat functional illness than protected products of mental hospitals for all their D.P.M.s (which for the purposes of this argument may be described as the barriers of neurology and terminology set up to hide the barrenness of official psychotherapy). In fact the vast bulk of the treatment of neurosis and incipient psychosis is left to the G.P. In theory too it should be recognized that many holders of D.P.M.s have poorer chances than many G.P.s of understanding the issues involved in functional illnesses.

It must be acknowledged that some form of training analysis, which helps the doctor to recognize in himself the tendencies exhibited by functionally ill patients, is of great assistance to the doctor. So there would be room alongside G.P.s in these much needed clinics for whole-time psychotherapists capable of providing training analyses and of tackling the most difficult cases. But thorough work on functional illness needs to be done by G.P.s if any effective impression is to be made on the mass of neurosis that afflicts our nation.

The question remains whether half a dozen or so hours a week are too much to ask from overburdened G.P.s. My answer is that the enlightenment they would gain by observing cures of neurosis would enable them to avoid wasting perhaps as much time on palliative treatment of symptoms, and they would also gain skill in dealing with other problems that overburden and debase them and their patients.

In support of the proposition that doctors with more general than specialized experience can, if they take the time and trouble, see cases of neurosis clear up before their eyes, I submit a report of a case in which the few interviews averaged less than half an hour each (with due acknowledgments for help and permission to publish to Dr. E. Graham Howe).

X., aged 27, with one child and a wife three months pregnant, complained of palpitations and dizziness following the death of his mother six months previously.

He was first assured that his dreams could throw light on his symptoms. Two days later he was back with a dream of visiting his wife in hospital to give her a ring; he was angry to find that she had lost her engagement ring; then she had turned into his mother. And he agreed with me that he might be reluctant to allow his wife to become the mother of his children rather than remain more of a mother to himself. He was asked why he was reluctant to allow such changes to happen. To the fourth interview he brought a dream of being in a dark tunnel with light showing dimly at the far end. And he was asked whether his change from the womb to the world had been difficult and whether he habitually found changes difficult. He came to the fifth interview with the information that he had been a 12-lb. baby, and that some years back he had slight palpitations and dizziness for a period of months prior to doing some growing up. By then he was free of symptoms and wanting to return to work. But he was back a week later confused and miserable, and was told that in him dark hours tended to precede dawns. He next appeared three weeks later, saying that he had stayed away from the provoker of such violent changes in himself, but gratefully reporting that he had worked through some previously repressed grief at the loss of his mother and had reviewed his stubborn reluctance to accept changes in a series of vivid memories. He was relieved and hopeful, and was prepared to live and work as the father of a family. His palpitations and dizziness were gone.

Neither this case report nor my provocative assertions can contain more than fragments of the truths involved. But that G.P.s should allow themselves to be stuck in the position of having eyes and seeing not and having ears and hearing not the facts about their patients' functional illnesses—no, Sir, it just cannot be done.—I am, etc.,

Ruislip, Middlesex.

WILLOUGHBY CLARK.

## Battle Neurosis Treated with Leucotomy

SIR,—Dr. D. W. Winnicott states (Dec. 13, p. 974) that he has lost hope that leucotomy will be refused by doctors to those who cry out for it. This kick from an eminent analyst calls for reproof. There is probably no harder or more lonely medical path nowadays than that of a thinking analyst or psychotherapist. With little or no interest from universities or colleagues, closed schools of thought, fantastically inadequate training facilities and educational propaganda, there is little to uphold such a worker except the courage of his patients who choose to work through analysis rather than gain relief by tissue destruction and the memory of past patients who are now whole and living full, useful lives.

Small wonder that many a young doctor is allowing himself to be shepherded. I will not yet use the word directed, along the broad highway of D.P.M. to a safe, established appointment, where all the latest methods of physical treatment are used. Educationally the present generation of doctors is probably more sinned against than sinning. Encouragement and help from high quarters rather than laments would be welcome.—I am, etc.,

London, W.1.

ALICE E. BUCK.

## The Waning Power of Penicillin

SIR,—I think the degree to which the power of penicillin is waning has been very much overemphasized. In my recent article "Staphylococcal Infection due to Penicillin-resistant Strains" (*British Medical Journal*, 1947, 2, 863) I was referring to a selected group of cases. A very high proportion of these patients had had penicillin before the swabs from which I isolated penicillin-resistant staphylococci were taken, and in other cases the infection probably occurred during their stay in hospital. While it is possible that institutions using large quantities of penicillin are breeding penicillin-resistant staphylococci at the expense of sensitive strains, it is very unlikely that this is happening to anything approaching the same degree in the community at large. Penicillin is still the most powerful weapon we possess against staphylococcal infection, and, while previously mentioned observations make it clear that its indiscriminate use should be avoided, it is of the utmost value in the treatment of such cases as Dr. Thyne refers to in his letter in your issue of Dec. 13 (p. 974).—I am, etc.,

London, W.12.

MARY BARBER.

SIR.—In all the literature on this matter that I have read the general explanation of reduced efficiency of penicillin seems to indicate that the bacteria have acquired a tolerance to penicillin by reason of small doses given in mild conditions, usually by local application. It ill becomes a general practitioner with no special knowledge of pharmacology to dispute this explanation, but it has occurred to me that the penicillin itself may have lost some of its potency by reason of long-continued cultivation of *Penicillium notatum* in the laboratory. The analogy of a bacterial culture of, say, *B. pestis* losing some of its virulence by culture *in vitro* might apply to penicillin.

After all, penicillin is a biological product and not a synthesized substance, and its rapid production under artificial conditions might adversely affect its potency. *P. notatum* in its natural state feeds on a large variety of organic substances, but commercially it is bred presumably on a very limited number of media. Can it be that *P. notatum* (like some of us) is getting tired of its monotonous diet and is losing some of its virility, if the latter quality can be attributed to a vegetable? Whatever the real explanation may be, it is certainly time that the experts investigated the matter. I am beginning to feel guilty whenever I prescribe a bottle of troch. penicillin.—I am, etc.,

Holcombe Rogus, Somerset.

J. V. MAINPRISE.

### Staphylococcal Infection by Penicillin-resistant Strains

SIR.—An important cause of the multiplication of penicillin-resistant strains of *Staphylococcus pyogenes* is the indiscriminate local use of penicillin in the treatment of skin diseases. Penicillin, at any rate in cream or ointment form, has little or no therapeutic value even in conditions generally regarded as superficial infections by pus cocci. Moreover, penicillin is responsible more or less directly for the conversion of many trivial and benign dermatoses into severe and troublesome cases of acute dermatitis.

Penicillin, originally puffed as a talisman of immunity on the battlefield, has been the subject of such intense advertisement that it is demanded by patients who, thanks to 50 years of compulsory education, can more or less recognizably lip its name. Our figures at the Skin Hospital correspond with those of Dr. Mary Barber (Nov. 29, p. 863). We have also seen several penicillin-resistant  $\beta$ -haemolytic streptococci.—I am, etc.,

Manchester.

J. H. TWISTON DAVIES.

### Penicillin in Scarlet Fever

SIR.—I was interested to read your annotation in the *Journal* of Dec. 6 (p. 915) on "Penicillin in Scarlet Fever," as I was the writer (French) of the paper in the *Journal of Hygiene* to which you make reference. I have to point out, however, that there is a printer's error in the reference you quote, as my paper on scarlet fever was published not in 1945 as stated, but in 1939 (Sept. 16). I think this is important, inasmuch as if my conclusions on the value of sulphonamides in scarlet fever stand unrefuted after a period of eight years more weight may be given to them than if they were only unrefuted for two years.

I may add that I have had a considerable experience of the treatment of scarlet fever since 1939, and I am still quite convinced that the sulphonamides are of little or no value—even the newer and less toxic varieties that have appeared since 1939. I am still equally far from knowing why they should be so useless. Perhaps someone with more opportunity than I now have will be able to elucidate this. I would also like to know the results of a properly controlled therapeutic trial of penicillin in scarlet fever. If you know of any such I would be much obliged if you would tell me about it.—I am, etc.,

Darwen, Lancs.

JANE O. MILLAR.

### Measles

SIR.—May I support Dr. Harwood Stevenson's advocacy (Dec. 6, p. 928) of the use of parental whole blood as a routine measure in the attenuation of measles in contacts, and particularly in the dangerous period up to the age of 5? It is a method particularly applicable to general practice, where as a rule attenuation and not prevention is the objective. There

can be little doubt that if this procedure were widely used there would be an appreciable drop in the death rate from measles.

In your leading article of June 29, 1946 (p. 991), there occurs this startling statement: "Despite the success which has been achieved in lowering the mortality from this disease it remains one of the largest causes of death among children." This fact alone would justify any safe method which could reasonably be expected to attenuate the disease, and in the *Journal* of June 30, 1945 (p. 923), I described a series of cases of 25 contacts so treated with most satisfactory results. An earlier series of cases of successful attenuation was described by Dr. T. D. Culbert (*British Medical Journal*, 1938, 2, 705). As regards dosage, I feel that if disappointment is to be avoided not less than 8 ml. of whole blood should be injected, and that it should not be reduced on account of the age of the child, for it is after all in the youngest contacts that attenuation is most important. (I do not think one would reduce the dose of diphtheria antitoxin because of the age of the patient.)

Finally, I would venture to suggest that Dr. Stevenson is a little optimistic if he expects any material attenuation when the blood is given "at any time up to the sixth or seventh day of incubation." This would probably succeed if one were using convalescent serum, but it would almost certainly fail to produce satisfactory attenuation in the case of whole blood and might well bring the method into disrepute. In my experience if it is to be really effective it should be given forthwith—that is to say, on the day when the fact of contact has been established or as soon after as possible.—I am, etc.,

London, N.W. 7.

A. H. MORLEY.

### Dogs and Poliomyelitis

SIR.—Dr. Norman Macfadyen's letter (Dec. 6, p. 930) is interesting because a paragraph in an evening paper a few days ago stated there has been an epidemic of paralysis in dogs in the eastern counties and that 300 cases had been reported: I have two "pekes," and last June one of them, after a day's malaise, became partially paralysed in her hind legs and tail. Recovery ensued in 14 days. Then a month afterwards the other, after 24 hours of lassitude, became totally paralysed in both hind legs and tail.

The lesion must have been in the dorsal cord, for both hind legs and the tail, and also the abdominal muscles, were spastic. The bladder function was unimpaired but the bowel was difficult from the loss of the muscles accessory to defaecation. The dog was very ill for a week and then got better, but the spastic paralysis remained unchanged for over two months and then recovery ensued, though the hind legs are still weak. Injury can be absolutely ruled out; and both dogs are beyond the age for distemper, and, moreover, there were no symptoms of it. It seems pretty certain that the condition was due to a virus, and the occurrence of such cases at the same time that an epidemic of anterior poliomyelitis is affecting the country is surely suggestive.—I am, etc.,

London, W.1.

VICTOR BONNEY.

### Chronic Sinusitis in Children

SIR.—Mr. F. M. Walker (Dec. 6, p. 908) raises the question of the treatment of chronic nasal sinusitis in children. This matter has been receiving attention at Warwick Hospital for some years, and the following observations may prove of interest.

In order to obviate the necessity of giving repeated general anaesthetics for antral washouts in cases that have not been cured by the use of nasal drops and attention to the general health, we have been placing a ureteric catheter into each infected antrum, some inches of the tube being strapped on to the opposite cheek, the extra-nasal end being wrapped in sterile gauze, following the technique described by R. H. Hunt Williams (*Proc. roy. Soc. Med.*, 1946, 39, 280). The antra have then been washed out from one to several times daily. Solutions we have been using are: "soluthiazole" 5%; ephedrine 0.5%; "flavazole" 1 in 2,500, with or without penicillin, 500 units per ml., in normal saline; isotonic or slightly hypertonic sodium chloride; proflavine 1 in 2,000 in normal saline.

In a recent American paper (the exact reference to which I am unable to trace at present) evidence was presented indicating that isotonic or somewhat hypertonic saline solutions were as effective therapeutically as solutions containing chemotherapeutic agents. On

a few occasions we used solutions containing several thousand units of penicillin per ml., but these sometimes caused excessive mucoid nasal discharge. A. W. Proetz (*Ann. Oto-laryng.*, 1945, 54, 94) has shown that concentrations of more than a few hundred units of penicillin per ml. interfere with ciliary action. The extranasal end of the catheter may be treated with a disinfectant before performing the washout. The amount of solution employed for each washout has varied from 7 to several hundred ml.

The lavages have been discontinued after there has been a return free from pus several times, or after a maximum period of three weeks, the catheter then being removed. A number of cases still having pus in the antra after such treatment for three weeks have been found to be free from sinusitis after a further month or two without treatment. Some others have been cured by staying in a convalescent home at the seaside. Vitamins in adequate amounts have also been administered to all these patients.

Cases not cured by such treatment have also not been cured by intranasal antrotomy, which we have found therapeutically inferior to it; also, children prefer antral lavages through a catheter as described to washouts through an antrotomy by the usual methods. These uncured cases, when the symptoms caused by the sinusitis have been sufficiently severe, have been treated by Caldwell-Luc operations, the diseased antral lining being removed. The youngest patient so treated was four years old, but in some older children also the antral cavity may be so small as to make the operation not feasible without damaging unerupted teeth. The results of this operation in children in general have been found satisfactory; no harm has resulted in any case; continuation of symptoms and signs of sinusitis is usually due to disease of other nasal sinuses, and in a few severe cases we have been able to relieve or cure them by intranasal, transantral, or external surgery to the ethmoid, sphenoid, or frontal sinuses.

In some unruly or small children who persist in pulling out the catheter we have followed the lead of G. H. Bateman (*J. Laryng.*, 1945, 60, 110), filling the antra once or twice with a paste containing penicillin, sulphathiazole, flavazole, soluthiazole, or several of these in lanette wax or plasma solution concentrated to the consistency of honey. A few cases have been cured, and some more temporarily relieved, by this method.

In our experience systemic penicillin or sulphonamide therapy for chronic nasal sinusitis, while temporarily relieving some cases, has nearly always failed to cure them. Proetz suction-displacement treatment we have also found disappointing. It has been our experience that the removal of tonsils and adenoids in cases of chronic sinusitis does not lead to its cure, that it is often more important to treat it than to remove the tonsils and adenoids, and that at any rate in very purulent cases it is best treated before this operation is done. Incidentally, bronchiectasis and chronic nasal sinusitis co-exist fairly frequently.—I am, etc.,

Warwick,

J. A. HARPMAN.

### Relief from Pain in Obstetrics

SIR.—It would be a fitting centenary tribute to Simpson if we could create and build up an adequate national organization for giving relief from pain in obstetrics. One hundred years ago James Young Simpson showed that the suffering endured by our young mothers could be reduced to a minimum, but his teaching was not understood. In 1933 R. J. Minnitt produced an automatic apparatus for the administration of gas-air analgesia; his teaching has been wilfully neglected. Can we never abolish the scandal of the "woman in pain"?

I have closely watched the results of gas-air analgesia when properly administered since November, 1933, and I have in my possession many hundreds of record papers signed by mothers stating that the vast majority of them were given adequate relief from pain. I am sorry to say that I have also received many letters from patients from all parts of England telling me of experience of indifferent analgesia. One writes: "One nurse in charge of a ward has told me that she always gives mothers the machine to use, but never turned it on." Another: "The birth of my own baby was a nightmare I shall never forget, and the gas-and-air machine provided in the County Council hospital . . . had no effect whatever." And this sad story is repeated over and over again. I know that these letters are true. I have many times visited hospitals and seen gas-air machines in such a condition that no help could be expected from their use. I have seen the gas and air administered in so careless a manner that one was left with the unhappy impression that those in charge of the administration did not care whether the patient was helped or not. Yet from the use of the latest models of gas-air machines it is possible to obtain complete

relief from pain in 95% of cases, and we have in addition the opportunity to use trilene and air, a promising newcomer.

There are two main causes for failure to give adequate analgesia: (a) lack of medical interest; (b) shortage of staff. (a) While the midwife is perfectly capable of taking charge of the administration of analgesia, yet she must have "medical interest" in her work. Machines and equipment need frequent examination by medical practitioners, as they sometimes need adjustment, and experienced practitioners should visit the labour ward to see that there is no error in the technique of administration. In all hospitals and in all districts there is need for the appointment of medical analgesists to help the midwives. The periodical visit from the manufacturer's agent is not enough. (b) There is an acute shortage of midwives, so that those in practice have too much to do. The demand for the provision of analgesia by the midwife may well be the last straw which is breaking the back of a very willing camel. If this is so, provision must be made for the creation of a body of nurse-technicians who must be trained to become "analgesists."

I criticize and condemn not the midwife nor the medical practitioner but the whole body of our countrymen and countrywomen, who callously allow hundreds of thousands of women to suffer the extremity of pain for the maximum of time when most efficient and adequate means of relief are available for the use of an organized analgesia service. Yet fourteen years after the introduction of the use of nitrous-oxide-and-air analgesia no such organization has been provided.

What a tale to tell of England one hundred years after Simpson's discovery! We have the knowledge of how to relieve pain, we have excellent machines designed for this purpose, we lack only a genuine national desire to help and an efficient national organization.—I am, etc.,

New Barnet, Herts.

JOHN ELANI.

### Obstetric Flying Squads

SIR.—The detailed account by Mr. Frank Stabler of the Newcastle-upon-Tyne Obstetric Emergency Service (Nov. 29, p. 878) must have been of great interest to many readers, especially in view of the way the development of the service has been dictated by local conditions. However, there is a danger that some may be misled into believing that the routine described is applicable to most obstetric emergencies, despite the author's remarks that "this centre is probably unique," and forgetting too the tremendous advances that have recently been made in resuscitation and transfusion, developed largely by the Army Transfusion Service.

The author's statement, "There is no doubt that the pregnant woman who has lost blood must be saved an ambulance journey," might lead one to suppose that cases of antepartum haemorrhage are best treated in the home. In most districts the opposite is true, and the emphasis should be placed upon non-interference, a strict ban on vaginal examination, adequate morphine, and admission to hospital as soon as the stage of primary shock is passed. The role of the flying squad should be that of a resuscitation unit for the continuous transfusion of the most severe cases during transit to hospital.

With reference to intra-partum emergencies, the statement, "The bad old system [my italics] of transporting these gravely ill and shocked women to hospital lessened their chances of subsequent recovery," is again open to criticism. In addition to blood transfusion and expert obstetrical handling these bad-risk cases require highly skilled anaesthesia, hospital nursing, and frequently the presence of assistants, if the occasional fatality is to be avoided. It would be interesting to know what part the anaesthetic played in the four recorded fatal cases of obstructed labour, while the obstetrician must indeed be a bold man who would set out to control a diabetic coma or tackle a ruptured uterus in the patient's home.

It is certainly among the immediate post-partum emergencies that the service finds its chief field of use, and the description of manual removal of the placenta as a life-saving operation is amply justified. Its hazards and drama may largely be removed by vigorous and enthusiastic blood transfusion pre-operatively. In those cases of retained unseparated placenta in which shock predominates over blood loss the use of "methedrine" will raise the blood pressure enough to ensure safety of operating; while thiopentone injected in small dosage into the transfusion tubing makes an admirable anaesthetic that may be administered by the relatively unskilled assistant.

In conclusion it is emphasized that in most districts the domiciliary treatment of ante-partum and intra-partum

emergencies is seldom in the patient's best interest, and an obstetric emergency service should consist primarily of an ambulance equipped as an efficient resuscitation unit with unlimited blood at its disposal. The obstetrician can thus ensure that he is not forced by circumstances to perform operations at home that would have a wider margin of safety in hospital.—I am, etc.,

Birmingham.

W. G. MILLS.

### Child-bearing and Tuberculosis

SIR,—Child-bearing and tuberculosis is still a subject which arouses strong feelings. We are grateful to your correspondents for their interest in our work and for some very appreciative remarks. We have endeavoured to make an objective judgment on this difficult subject, but we hope our figures are a sufficient basis for an opinion. It cannot be denied that the tuberculous disease in some patients becomes worse in association with pregnancy. This is a habit of tuberculous disease in non-pregnant women too, and in our experience equally common in both groups.

We too wish to emphasize the importance of the environment of the tuberculous woman who has borne a child. Efficient treatment of the disease and the best possible after-care with adequate home help are especially necessary for these patients. Whether therapeutic termination of pregnancy is advisable because the child will be born into an unsuitable environment is a moot point, but such a view would cause the termination of many more pregnancies than those of tuberculous women. Because tuberculosis carries a definite risk of relapse, we think that the patient should avoid pregnancy for at least two years after quiescence of the disease has been achieved. Yet only 22 (10%) of the patients in our series were diagnosed as tuberculous after becoming pregnant. We are surprised how often effective (or indeed any) advice concerning birth control is lacking. Of these 22, 11 were over fourteen weeks pregnant; few would advise termination at such a stage. We therefore consider that good treatment and care in adjusting the environment, including the effective prevention of pregnancy where advisable, are more important than undue optimism about the value of therapeutic abortion.—We are, etc.,

CHARLES J. STEWART.

F. A. H. SIMMONDS.

South Mimms, Barnet, Herts.

### "True" Hermaphroditism?

SIR,—Without splitting too many semantic hairs, is there any such thing as "true" hermaphroditism? Whatever gross abnormalities may subsequently be induced by hormone imbalance, what one might term the *fundamental sex* of the individual is determined once and for all at the moment of conception by a particular combination of chromosomes that apparently persists for life. Current theory does not allow for both xx and xy combinations to co-exist in one body, though in biology even the fantastic cannot be excluded. Have the chromosomes of frank hermaphrodites ever been seriously studied? The forensic implications are enormous.—I am, etc.,

Hooton, Cheshire.

J. R. EDISBURY.

### Routine Serological Tests for Syphilis

SIR.—The letter of Dr. K. G. Bergin (Dec. 6, p. 928) merits some comment. Routine serological tests are carried out in many antenatal clinics, etc., throughout the country, and with competent technique, as part of the established routine, attract no more comment from patients than the routine testing of the urine or taking of blood pressure. Where difficulties have arisen, these have in my experience most often resulted from the attitude of the medical officer or nurse, and have not been raised primarily by the patient. It is also instructive that patients accustomed to routine serological tests as part of routine antenatal surveillance comment adversely on this omission in other areas in which they may be temporarily absent.

In the City and County of Bristol approximately 75% (approximately 5,000 per annum) of pregnant women attend the health department clinics for antenatal care. Serological tests or the exclusion of syphilis have been carried out routinely since 1939, in not more than one or two cases per annum has the test been refused. Syphilis, previously undetected, has been found in less than 0.4% of patients. Facilities for the examina-

tion of serological tests would therefore be of little added advantage so far as the patients making use of the municipal services are concerned, and it is questionable whether this principle should be adopted until voluntary measures, supported by adequate health education, are shown to have failed.

With regard to marriage, surely a general medical overhaul to make certain of physical fitness is the ideal. The exclusion of tuberculosis is equally as important as negative syphilis serology, while Rh compatibility equally deserves consideration. In the past few years there has been an increasing number of patients, often of blameless antecedents—frequently engaged couples coming up together—desiring assurance of fitness for marriage, the main anxieties being venereal disease, tuberculosis, and fertility.—I am, etc.,

Bristol.

A. E. W. McLACHLAN.

### Belladonna Poisoning

SIR,—I am sure that your correspondent "R. L. G. R.A.F.V.R." (Nov. 29, p. 886) must be aware of the rules governing the storage and dispensing of the Schedule I group of poisons, which I believe includes belladonna preparations. I am therefore at a loss to understand why he had to discover "later" that it was contrary to Air Force regulations for a nursing orderly to dispense belladonna unsupervised. During my own Service career I have, through "supervising" the activities of orderlies in a station sick-quarters M.I. room, prevented disasters of like nature—e.g., concentrated phenol being used in mistake for glycerin-and-phenol ear drops; strong tincture of iodine in lieu of "argyrol" eye drops; and saturated sodium sulphate with acriflavine instead of sodium salicylate mixture.

It should always be remembered by those concerned that the so-called "nursing orderlies" in the present-day Royal Air Force may be (and too often are) unwilling conscripts, whose eyes are more accurately focused on the "demob. form" than on the labels of the dispensary bottles.—I am, etc.,

PER ARDUA AD ASYLUM.

### Nicotinamide and Blood Sugar

SIR,—I was very much interested in the two cases of diabetes mellitus described by Dr. L. Gordon (Nov. 8, p. 748). The following is another unusual case of this disease which merits publication.

#### CASE REPORT

C. W., aged 54, was admitted to our hospital on Sept. 7, 1947, as he was anxious for an operation for a large irreducible umbilical hernia which was causing disfigurement. He complained of no other symptoms, and except for mild hypertension there were no abnormal signs. Height: 5 ft. 9 in. (1.75 m.); weight: 15 st. 5 lb. (95.2 kg.). Routine examination of urine showed specific gravity 1022, glycosuria, and ketonuria. Blood-sugar curve was typical of diabetes mellitus and gave the following figures:

Time of Day	Sugar in mg. per 100 ml.	Urinary Sugar
9 a.m. .. .. .	210	++
9.30 " .. .. .	280	++
10 " .. .. .	340	++
10.30 " .. .. .	300	++
11 " .. .. .	265	++

He was stabilized on a 2,000-caloric diet with 20 units of soluble insulin and 30 units of protamine-zinc insulin every morning. Operation under local analgesia was performed by Mr. T. Eason on Oct. 8, 1947. Hernial sac containing adherent mass of omentum was excised and the wound was closed by through-and-through mattress sutures. Immediately following this operation he was free from glycosuria, needed no insulin, and two days later he was put on ordinary diet without any adverse effects. Blood-sugar curve was now of lag variety and gave the following figures:

Time of Day	Sugar in mg. per 100 ml.	Urinary Sugar
9 a.m. .. .. .	110	Nil
9.30 " .. .. .	175	
10 " .. .. .	195	Trace
10.30 " .. .. .	200	
11 " .. .. .	172	Nil

Remissions in diabetes mellitus are well known, but the above case showed dramatic improvement after the operation, needing no insulin in spite of the subcutaneous tissue becoming

septic and the wound taking some time to heal. As the hernial sac contained a mass of omentum, is it possible that this immediate improvement is caused by improved pancreatic circulation? Vasodilatation follows the administration of nicotinamide, as shown by flushing of the face, etc., and it is suggested that apart from the role of nicotinic acid in carbohydrate metabolism the beneficial effects of this drug in diabetes mellitus may partially be due to improved pancreatic circulation, and that this effect will vary with the dosage.

The patient is now in good health and has lost 11 lb. (5 kg.) in weight. He was a heavy beer-drinker prior to his admission, but he now drinks only a pint a day, and this may be a contributory factor in maintaining the improvement. I would be glad to hear your readers' views on the above case.—I am, etc.,

London, S.E.18.

S. KARANI.

### Leukanaemia and Myelosclerosis

SIR,—I wish to enter a plea for the retention of the term "leukanaemia" in regard to cases of what is now termed leuco-erythroblastic anaemia, with clinical or post-mortem evidence that a greatly damaged haemopoietic activity of the bone marrow has been supplemented by extramedullary haemopoiesis in the spleen and probably liver ("megakaryocytic" splenomegaly and megakaryocytic hepatomegaly) and possibly in lymph glands. It will, however, be convenient to exclude those cases in which the failure of medullary haemopoiesis is due to carcinomatous infiltration or other neoplastic destruction of the bone marrow. The term "leukanaemia" would then be restricted to cases in which the bone-marrow failure is due to myelophthisis or fibrotic change (myelofibrosis, if this hybrid name is permissible) or to any kind of "myelosclerosis" in which the bone marrow is gradually destroyed or replaced by non-neoplastic endosteal osteoid or osseous formation. The term "myelo-osteosclerosis" would distinguish such cases of bony myelosclerosis from "myelofibrosis."

A typical example of "leukanaemia," in the sense in which I propose to retain the term, was that which I described in 1904 under the heading "A Case of Leukanaemia with Great Hyperplasia of the Spleen and Prevertebral Haemolymph Glands and with Increase of Connective Tissue in the Bone Marrow" (*British Medical Journal*, 1904, 1, 1416, and *Trans. path. Soc. Lond.*, 1904, 55, 288). The patient was a man aged 58 years admitted to hospital suffering from great anaemia, progressive weakness, anorexia, and tinnitus. These symptoms had developed during the last twelve months; in fact, he had apparently been able to insure his life about one year before admission. He had lived in England since 1865 and had never had malaria or been out of Europe. Together with the leuco-erythroblastic anaemia there was great enlargement of the spleen and liver. At the necropsy the marrow of the shaft of the left humerus was carefully examined and found to have undergone transformation into a red substance of unusually firm consistence. This myelofibrosis was confirmed by microscopical examination. In sections of the spleen, liver, and kidneys there was absence of any reaction for free iron such as is found in pernicious anaemia. I concluded: "It is very tempting to suggest that the spleen (haemal gland) and the prevertebral haemolymph glands were actively engaged in supplementing the erythrocyte-forming functions of the diseased bone marrow." I alluded also to what French authors (as Vaquez and Aubertin) termed "anémie splénique myéloïde." In a later paper (*Mcd. Pr.*, 1928, 176, 174) I recorded another report, by Sir J. C. G. Ledingham, who kindly made a microscopical examination of the organs from my case after the one which I had reported. He drew attention to the peculiar type of myeloid transformation in the liver. "There were," he said, "numerous areas of veritable marrow, with extraordinary numbers of megakaryocytes, which occasionally showed mitosis. Some of the megakaryocytes were so large that they would not possibly have passed through the fine interacinous capillaries."

I borrowed the term "leukanaemia" from W. von Leube and from Arneht's haematological account of von Leube's case (*Dtsch. Arch. klin. Med.*, 1901, 69, 331) and H. Luce's paper (*Ibid.*, 1903, 77, 215), though my case was not exactly similar. I suppose now that my case must be classified among the cases of myelofibrosis of uncertain aetiology, with resulting sympto-

matic leuco-erythroblastic anaemia. G. Carpenter and C. M. Flory (*Arch. intern. Med.*, 1941, 67, 489) have headed a recent paper: "Chronic Non-leukaemic Myelosis: Report of a Case with Megakaryocytic Myeloid Splenomegaly, Leuco-erythroblastic Anaemia, Generalized Osteosclerosis, and Myelofibrosis." As explained by L. A. Erf and P. A. Herbert (*Ann. intern. Med.*, 1944, 21, 863), myelofibrosis is not of course synonymous with aplastic anaemia. The bone marrow in the former is fibrotic and in the latter it is fatty. Extramedullary haemopoiesis exists in the former but not in the latter.

An important clinical point is that in "leukanaemia," as I propose to limit the term, splenectomy is, as has been often pointed out, absolutely contraindicated, because the enlarged spleen (part of the conservative mechanism of extramedullary haemopoiesis) is helping to keep the patient alive.

Incidentally, I should like to know whether the condition of "polyostotic focal fibrous dysplasia" (in which I would include cases of "Albright's disease") ever leads to a condition of leuco-erythroblastic anaemia, in fact, to leukanaemia, in the restricted sense of the term which I advocate. Another question: Can there be gelatinous degeneration of bone marrow, such as is occasionally met with at post-mortem examinations, which is not merely a *paulo-ante-mortem* phenomenon but may allow the patient to live long enough to develop a resulting condition of myelofibrosis?—I am, etc.,

London, W.1.

F. PARKES WEBER.

### Pelvic Sympathectomy

SIR,—I was interested to read that Prof. J. P. Greenhill (Nov. 29, p. 859) advises pelvic sympathectomy "in cases of endometriosis in which conservatism is advisable." I agree wholeheartedly. Indeed, I have practised this for some time, and in addition I suspend the uterus to prevent retroversion due to adhesions. But I do not think Prof. Greenhill's technique goes far enough. It should be noted that he describes his operation as "Pelvic Sympathectomy" and not "Presacral Neurectomy." But he does not completely denervate the ovaries, and since endometriosis so frequently involves the ovaries it is very important to include them. Your annotator in the same issue mentioned this point with reference to the work of O'Donel Browne (1939) in the treatment of ovarian dysmenorrhoea.

Mitchell (1938) summarizes the nerves to the ovary as follows: (a) A superior group from the intermesenteric nerves and from the renal plexus. (b) A middle or intermediate group from the superior hypogastric plexus or from the hypogastric nerve. . . . It is possible that the nerve supply to the ovary may be mainly sympathetic in nature, and confined to those nerves described above as the superior and middle ovarian nerves. The inferior ovarian nerves supply filaments both to the uterus and tubes but few (if any) to the ovaries." Therefore in addition to presacral neurectomy I feel it advisable to incise the infundibulo-pelvic ligaments to complete the pelvic sympathectomy. In many cases of endometriosis this will be necessary on one side only, because pathology in the opposite ovary has already necessitated its removal.—I am, etc.,

Oxford.

### A Medico-Nursing Society

SIR,—It is only in recent years that the importance of post-graduate medical education has received appropriate recognition. As far as nurses are concerned, however, such education is neglected and sometimes even ignored. The problem of maintaining the interests of nurses alert and up to date is not less urgent than the similar problem in relation to doctors. When I arrived at St. Bernard's Hospital as Deputy Medical Superintendent, after several years away in the R.A.M.C., a number of senior nurses requested my help in keeping their knowledge of modern developments in psychiatry and nursing abreast of the times. I found the matter presented many difficulties, such as the fact that the majority of senior male nurses and a large number of the female ones live out of hospital, most of them being married and having family obligations. After due consideration I concluded that a mere series of lectures would not in itself suffice. I sought to devise a scheme that would attract

a large number of the nursing staff and not be confined to a few enthusiasts and one that could endure perennially rather than flourish for a short time and then fade out.

Eventually I decided the solution was the formation of a society among the nurses resembling as closely as possible in function and purpose a medical society among doctors, and thus arose the St. Bernard's Hospital Medico-Nursing Society. This society has now existed for a year and continues to thrive. Since in my estimation it has so far fulfilled the purpose for which it was formed, I think it is worth while giving a brief description of its organization and activities in the hope that they may form a prototype for the formation of similar societies in other hospitals.

The society is a medico-nursing society and confines its activities to medical and nursing subjects. Discussion of administrative and pecuniary organizations and grievances is not permitted. Membership of the society is open to (1) anyone on the male or female nursing staffs, whether they be of graduate, undergraduate, student, or temporary category; (2) auxiliary personnel such as the physiotherapist, dispenser, occupation therapist, and pathological technician; (3) the hospital doctors. Members attend all club activities in their off-duty hours.

The society is administered by a committee elected by members once every year and composed of: a chairman who is a doctor (and in this case myself); two members of the senior male staff, two members of the senior female staff, and the senior tutor. Recently this has been augmented by one male and one female member of the junior—i.e., unqualified—staffs.

Meetings of the society are held once every three weeks on Mondays at 9.30 p.m. (coffee served at 9.15 p.m.) in the nurses' home. The object of holding the meetings so late is to allow the afternoon shift time to have a quick meal before coming to the meeting, and the interval between meetings is an odd number of weeks so that the shift on afternoon duty alternates from one meeting to the next. Meetings are confined to the months from October to May inclusive. Membership incurs no financial obligation and no subscriptions are demanded.

The principal functions of the society are a series of lectures, discussions, films, etc., that will prove interesting and instructive. The choice of subjects is made by members at the annual general meetings and it is left to the discretion of the committee to arrange details. Up-to-date lectures followed by discussions have been given on the following subjects: the endocrine glands; the effects of insulin and convulsive therapies; infantile paralysis and virus infections of the C.N.S. (films were shown in each case); the legal aspects of psychiatry; social and recreational activities in the treatment of psychiatric patients; recent advances in medical and surgical nursing and in the nursing profession; and tuberculosis. Two "brains trusts" have been held. The committee also hope to arrange occasional outings to places of interest such as an observation ward, a mental-defective colony, etc. The activities of the club do not preclude holding postgraduate lectures as part of the routine hospital education and a course of such lectures is now being given.

With regard to the meetings held the following points are noteworthy: (1) It is important to allow adequate time for a discussion following the address. Members greatly appreciate the opportunity to ask the lecturer questions. (2) The "brains trusts" were the most popular single events according to the opinion expressed at the annual meeting. (3) Short films were popular when followed by an explanation from the lecturer.

In conclusion may I say that any members of the medical and nursing professions who may wish to attend a meeting of this society to see how it functions will be welcome. If they communicate with the secretary or myself they will be advised of the future programme.—I am, etc.,

St. Bernard's Hospital, Southall, Middlesex

DONALD BLAIR.

### Yeast Extracts and Fat Absorption in Sprue

SIR,—Drs. D. A. K. Black and L. P. Fourman (Dec. 6, p. 928) do not deal with my criticism of judging the effects of yeast extract when combined with other therapy. My remarks were based partly on the data published in the article to which they refer, where the fallacy I mention is laid out clearly in tabulated form. Other data on which my view is based were obtained from observation of cases we studied on the Sprue Research Unit at Poona. I am interested to hear that they are treating cases of sprue in this country on yeast extract alone and maintaining them in remission. I am finding that maintenance in clinical remission in this country is in most cases achieved without any treatment at all.—I am, etc.,

Staines, Middlesex.

K. D. KEELE.

## POINTS FROM LETTERS

### Diet and the Nation's Health

Dr. R. E. CLARKE (St. Osyth, Essex) writes: I have read the report of the Hunterian Society meeting on diet and the nation's health (Nov. 29, p. 882). It was rather like a discussion between a test-tube or a laboratory guinea-pig or statistician and a family doctor. . . . Like many others I have been in the same practice for some years before the war, during the war, and since the war in an 80% rural practice with a fair sprinkling of small-moneyed pensioners and a large percentage of over 70s. Without the slightest shadow of a doubt skin troubles are many times what they used to be, digestive troubles the same, eye troubles in the shape of styes and blepharitis, inflammatory conditions following insect bites, and pricks of all sorts; anxiety states in women particularly are rampant. Here I will ask the diet experts how many calories are needed to counter the wear and tear of the body of a woman who spends an hour or two trying to get some food or clothes for the family. . . . We probably cannot be better fed at the moment, but as a profession we should not encourage the idea that we are satisfactorily fed, by talking calories and vitamins. The people themselves know that they are not nearly so well fed as before the war or even during the war.

Dr. R. M. NOORDIN (Ilford, Essex) writes: Dr. Westman (Dec. 6, p. 926) suggests that heroes are produced by misery; he ignores the thousands who died both in Germany and Russia during famine years. Those who survived were tough—very tough indeed. But it is the duty of civilization not to produce "tough heroes" (often beasts at heart) but to care for their health and build a normal nation.

### Guild of St. Luke (Anglican)

Dr. R. KELSON FORD (St. Stephen's Hospital, Fulham Road, London, S.W.10) writes: I shall be grateful if any reader can give me any information regarding the (Anglican) Guild of St. Luke. Before the recent war annual services were arranged in St. Paul's Cathedral, and the last secretary traced (Rev. Dr. Bhabha) died in 1941.

### Diet and the Nation's Health

Mr. J. BURDON-COOPER (Barrhill, Ayrshire) writes: I refer to the letter from Dr. F. M. R. Walshe (Dec. 13, p. 971). I should think it is hardly possible that there will be anyone occupied in clinical work, or whose daily work concerns the health of the people of this nation, who will fail to endorse the views he has expressed in his letter. Dr. Walshe is adept at the *mot juste*, as his students and clinical clerks knew so well, and in this instance he exactly hits the nail on the head. What he has said has needed to be said for some time now, and it is to be hoped that it will be duly noted.

### Physical Development

Capt. C. LIFFE (Richmond, Yorks) writes: After having the honour to spend six years as a serving soldier, one tends to look at the civilian medical service with a more critical eye than one did before the war, and among the many shortcomings one finds the lack of any serious provision for the development of the mental and physical weed is one of the most striking. . . . Physical-development centres set up in different parts of the country, to which young persons of both sexes could be sent for six months or longer, there to be fed well and given intensive and carefully graded physical training under expert guidance, would be a piece of high-minded and far-seeing statesmanship. The matter would not be difficult. There are plenty of P.T. instructors available and enough medical officers who have been trained in just this duty. Suitable buildings could be found because distance from home would not matter. Only a few rules would be necessary. Obey or go; be cheerful; try hard—in fact, "Come if you are willing, put yourself mind and body into our hands for a time, and then go back home with a straight back and your head held high fearing nothing any more."

### Retained Placenta

Dr. K. M. LITTLE (Walsingham, Norfolk) writes: Put the baby to suck at the nipple if the placenta does not follow in, say, 15 minutes. In about 2 to 3 minutes the mother has a great contraction, which rapidly expels the placenta. Of course this does not apply to a real retained placenta. Also occasionally the nipple is not big enough to be sucked. But it is certainly well worth a trial.

Twenty-five holders of United Nations Fellowships have arrived in Britain from Austria, China, Czechoslovakia, Greece, Poland, and Yugoslavia. They will remain in this country for from six to nine months and will study such subjects as the rehabilitation of the disabled, the manufacture of artificial limbs, the instruction of the blind, deaf, and dumb, and the social aspects of housing, medicine, and industry.

TRADE MARK

**'SULPHATRIAD'**

BRAND

*compound sulphonamide tablets*

'SULPHATRIAD' contains, in each tablet:

sulphathiazole ..	0.185 gramme
sulphadiazine ..	0.185 gramme
sulphamerazine ..	0.130 gramme

We are pleased to announce that supplies of 'SULPHATRIAD' are now available through the usual trade channels.

'SULPHATRIAD' is suggested in the treatment of acute infections due to pneumococci, gonococci, meningococci,  $\beta$ -haemolytic streptococci, *Bact. coli*, *H. ducreyi*, and in gas gangrene. It may also be used as an adjuvant to penicillin therapy in grave *S. aureus* infections and in the treatment of localised staphylococcal infections such as boils, carbuncles and whitlows.

Since the solubility in the urine of each of the constituents of 'SULPHATRIAD' is not affected by the presence of the other two, the risk of renal complications such as crystalluria during treatment with this combination of sulphonamides is greatly reduced. Such a combination may also have certain advantages from the point of view of therapeutic activity.

GOOD RESULTS—EVEN IN ADVERSE CONDITIONS

**Ensign STANDARD X-RAY FILM**

Fine definition, excellent contrast, sparkling cleanliness—these are obtained by the use of Ensign Standard X-Ray Films—even when conditions in X-ray room and dark room are not favourable. The film has normal speed and exceptional latitude. The finest definition is obtained because of the freedom from fog. Variations in exposure times can be adjusted in development without materially affecting the quality of the finished radiograph. Whenever speed is not of primary importance Ensign Standard will achieve the desired results.

## *the NEW analgesic...*

First reports on the use of 'Physeptone' in general practice indicate that an outstanding advance has been made in the treatment of severe pain. With few exceptions, it may with advantage replace morphine, to which it is equal or superior in analgesic effect. 'Physeptone' does not unduly depress respiration, constipate, or induce narcosis or mental apathy; it may be given continuously for long periods without diminution of effect.

'Physeptone' is available in ampoules of 10 mgm. in 1 c.c., in boxes of 12 at 9/-, plus 2/3 purchase tax. For oral administration it is available as 'Tabloid' brand compressed products, 5 mgm., in bottles of 25 at 4/6, plus 1/1½ purchase tax, and bottles of 100 at 16/10, plus 4/2½ purchase tax.

## Obituary

### SIR BERNARD SPILSBURY, M.B., F.R.C.P.

Sir Bernard Spilsbury, whose sudden and tragic death took place in his laboratory at University College, London, on Dec. 17, was one of the most distinguished figures in forensic medicine. Sir Bernard was inevitably associated in the public mind with the unravelling of sensational crimes, and the high-lights were always upon him when he appeared, as he frequently did in the course of twenty-five years, in the witness-box in trials in which the crime had been of an unusual character. But among those best qualified to judge he had a greater reputation as an outstanding authority on the medical investigation of causes of death. For many years "Spilsbury Called In" was the favourite newspaper headline for the prelude to a story of murder or manslaughter to which some elements of mystery attached; but his best work was seen on the one hand in the patient investigation of innumerable cases which had no particular public interest, and on the other in the quieter paths of teaching, at which he excelled.

(Russell, London)

Bernard Henry Spilsbury, the son of a chemical manufacturer, was born in 1877. He was educated at Manchester Grammar School, and went on to

Magdalen College, Oxford, taking his B.A. in 1899 and proceeding to St. Mary's Hospital, London, where he qualified in 1905. At St. Mary's he came under the tutelage of the late Sir Almröth Wright, principal of the Institute of Pathology and Research, and his early work was in the bacteriological field. His first paper, contributed to the *Transactions of the Clinical Society* in the year of his qualification, was on pneumonia caused by *B. typhosus* in the course of enteric fever. Presently he became pathologist, lecturer in pathology, and curator of the museum at St. Mary's. His bent towards morbid anatomy was due to the influence of three brilliant men attached to St. Mary's at that time—namely, A. J. Pepper, the Home Office pathologist; A. P. Luff, scientific analyst to the Home Office from 1892 to 1908, who had become widely known in criminal investigation; and William Willcox, who had lately taken up the appointment as lecturer on chemical pathology and lecturer on forensic medicine at St. Mary's which he was to hold for thirty years.

With these three men Spilsbury was associated in his first famous case—the case of "Dr." Crippen, who was convicted in 1910 of wife-murder. As a result of the patient investigation of human remains found in the cellar of a house in Camden Town a fraction of a grain of hyoscine hydrobromide was isolated from portions of the viscera of the victim five months after the murder. In that same year, 1910, Spilsbury succeeded Pepper as pathologist to the Home Office, and so began his connexion with many celebrated trials which continued until he retired from active work of this kind, retaining the title of honorary pathologist to the Home Office, in 1934. He was knighted in 1923.

Spilsbury had exactly the qualities needed for such a position. He was patient in his investigations, bringing to them a disciplined mind, a critical and unprejudiced consideration, and the utmost care in arriving at his conclusions. His note-taking was voluminous; he was documented even on the most minor points, and the case-books filled with his neat writing must be a unique record in the history of crime. If his methods of investigation were beyond reproach, the presentation of his facts was equally admirable. Once, in an address to the West London Medical Society, he described the perfect medical witness, and warned doctors who had to go into the witness-box against prolixity, indistinctness, the use of jargon or superlatives, exaggeration, bias, and loss of temper. None could

accuse him of any of these faults. He was a witness after the judge's heart, giving his evidence in clear-cut fashion, never declamatory or violent in assertion, but always sure of his case and speaking with unmistakable authority.

He was lecturer in morbid anatomy at St. Bartholomew's, and in forensic medicine and toxicology at the London School of Medicine for Women; he was examiner in forensic medicine at different times to six English universities, and in pathology to the University of London. In 1913 he contributed a paper to the International Congress of Medicine on the pathological aspects of deaths under anaesthetics. During the first world war, like his colleague, Sir William Willcox, he made a special study of toxic jaundice, especially in munition workers, and presented the results to the Royal Society of Medicine. In 1924 he was Lettsomian lecturer to the Medical Society of London, taking as his theme wounds and other injuries. In 1932 he was vice-president of the Section of Forensic Medicine at the Centenary Meeting of the British Medical Association, and contributed to a discussion on the pathologist in coroners' courts, urging that the proper person to make a medico-legal examination of a dead body was an experienced pathologist who could also carry out any laboratory investigations that might be necessary. For many years he was secretary to the Medico-Legal Society, and contributed numerous papers to its proceedings, notably one on the medical investigation of crimes of violence. In 1933 he was president of that Society; his address from the chair was on certain forms of death, particularly in relation to criminal abortion. Beyond the papers which he contributed to the various societies he wrote very little, though it is understood that he had for some years been engaged in the preparation of a standard work on medical jurisprudence. His system of complete record-taking and careful indexing should make it possible for some other hand to complete the work. He became M.R.C.P. in 1924 and F.R.C.P. in 1931.

Spilsbury was not so immersed in morbid anatomy as to be indifferent to other aspects of criminal investigation. He had peculiar opportunities of studying the psychology of murderers, in particular the way in which they bore their burden of secrecy. He once gave it as his view that the murderer was impelled to make some oblique reference, if not a complete confession, to his act before his apprehension. The murderer, he said, turned the crime over and over in his mind until he arrived at some self-justification and wittingly or unwittingly gave voice to it. He had also noted the desire of many murderers for publicity. One of his first cases was that of the notorious murderer Seddon, and Spilsbury told how he had watched Seddon move eagerly to the police-court window where the press photographer could take his portrait.

In appearance Sir Bernard Spilsbury was the very opposite of what might be expected in a man whose preoccupation was with the macabre. His jovial, fresh-coloured face, his invariably correct attire, and little touches such as the flower in his buttonhole gave him the look of contented prosperity. His love for flowers and music—he was frequently seen at concerts if Beethoven or Mozart was on the programme—was well known. But in recent years he had had more than one illness, and those in close touch with him in the pharmacological department of University College, Gower Street, where he continued to work, and work hard, noticed how much he had aged. Tragedy had overtaken him in the death of two of his sons, one of them, Alan, closely associated with his father's work, and the other, Peter Bernard, who was on the threshold of his medical career when he was killed in the destruction of a part of St. Thomas's Hospital during an air attack on London in 1940.

WILLIAM CHARLES BENTALL died at Hindhead on Nov. 16 at the age of 73, after four months' illness. He studied medicine in Edinburgh, being associated with the Edinburgh Medical Mission, and shortly after qualifying, in 1901, he went to India as a medical missionary under the London Missionary Society. He became one of a line of outstanding medical men who built up the reputation of the South Travancore Medical Mission, which had a central hospital at Neyyoor and outstations and became one of the largest medical missions in the world. He settled in general practice in Southport in 1908, and threw himself with his accustomed energy not only into his professional

work but into the service of the St. John Ambulance Brigade and the board of directors of the London Missionary Society. In the Order of St. John he rose to be a knight and assistant surgeon-in-chief of the Brigade. The London Missionary Society honoured him by three times electing him chairman of the board. In his practice he was loved and honoured by his patients, and he built up a considerable reputation as a general surgeon. He was a good committee man and a capable organizer, and on his retirement from practice, in 1934, his services were soon sought by the growing A.R.P. organization. He was appointed assistant hospital officer for the South-Eastern District. After the cessation of hostilities, although seventy, he continued to serve on pension boards and committees, and in such leisure time as he allowed himself he cultivated his garden in Sussex. William Bentall was an enthusiastic traveller, and many of his holidays with his family were spent in Europe and further afield. His photographs were made into lantern slides, and his travel lectures were greatly appreciated by literary and lecture societies all over England. Those who knew him will always remember his quick boyish smile, his clear and impressive way of putting a case, his enthusiasm for any good cause, and above all his tireless energy. He leaves a widow, a son who is a doctor, and two daughters.—I. M. O.

Dr. JOHN MILLER YOUNG, who was the chief executive school medical officer for Glasgow, died suddenly on Nov. 20 at the age of 56. Dr. Young graduated M.B., Ch.B. at Glasgow University in 1914. Shortly after graduation he served in the R.A.M.C. as battalion medical officer to the 15th H.L.I. (City of Glasgow Tramways Battalion). For his services in France he was awarded the Military Cross. Unfortunately, he was so severely wounded in action that he had to undergo amputation of a leg, and his normally robust constitution was severely undermined. At no time, however, did he ever refer to his disability with any bitterness. On the rare occasions on which he did mention the injury he did so with a calm matter-of-factness which was all the more surprising in one who, in his early manhood, had been an athlete of repute. He took the D.P.H. in 1920, and became a Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow six years later.

J. M. writes: Young was endowed with an essential sanity of outlook and singleness of purpose; zeal for his profession and thoroughness in execution were his dominant characteristics. In council his words were well weighed, and his criticism was always constructive. Though of somewhat austere aspect, Young was at heart one of the kindest of men and was always ready to place at the disposal of those who were in doubt or difficulty the fruits of his extensive professional experience. He never spared himself in the exercise of his duties, and the high standard which he set for himself he expected from his staff. But he was intolerant of inefficiency or complacency. Apart from his more immediate professional duties Young was a man of many interests, and his work in the Association of School Medical Officers for Scotland, of which he was honorary secretary for many years, was characterized by the same enthusiasm and thoroughness that marked all his work. The Association owes him a debt of gratitude that can never be repaid. At the time of his death Young was a member of the Scottish Council for Research in Education, and was chairman of the committee investigating the sociological conditions of school-children in connexion with the mental survey at present being conducted by the Council. As one who was intimately connected with Dr. Young for a long period of years, both as a friend and a fellow medical officer, I should like to put on record the outstanding place he held in the esteem of his colleagues. His death in the full flower of his career is a grievous loss, and the niche which he occupied in the school medical service will be indeed difficult to fill.

Dr. JOHN RICHARD LARSON died suddenly on Nov. 30 at his home in Birstall, Leicester, where he was in practice for over twenty-five years. His parents were well-known Swedish missionaries in the Middle East, and Richard Larson was born in Tiflis about fifty-four years ago. He was always a good linguist, and spoke seven languages. In his early days at burgh he took a great interest in his fellow students and a leading light in the International Club. He took the triple qualification in 1919 and two years later graduated M.B., Ch.B. at Edinburgh. Naturally he followed in the steps of his parents, and later became superintendent of the Swedish Hospital in Bethlehem, from 1921 to 1923. It was a great disappointment to him when he had to retire from this post on account of the ill-health of his wife and young family. He returned to practice in Leicester, where he had previously held a resident's post at the Royal Infirmary. He was a member of Birstall Parish Council for many years, a freemason, and divisional surgeon of the St. John Ambulance Brigade. Despite the demands of a busy practice, he led a

very full life during the war, and became local A.R.P. instructor and examiner, and was a serving brother of the Order of St. John of Jerusalem. Richard Larson never would spare himself, and now we mourn an unselfish and loyal friend. His numerous patients will miss his many acts of kindness apart from his professional skill. He leaves a widow, a daughter, and a son.—C. Y.

Dr. WILLIAM FERRIDAY JACKSON died at the Manchester Royal Infirmary on Dec. 1 after a motor accident. He qualified M.B., Ch.B. at Owens College in 1897 and took the conjoint diploma in 1899. He was senior house-surgeon to Ancoats Hospital before taking up private practice in Ardwick. He served that area faithfully even up to the time of his death. A surgical colleague described him in simple words: "This gentle character was a real ornament to the profession and was an outstanding general practitioner." Jackson was a big-hearted man who did much good. He was self-effacing but ever ready to lend a helping hand, a philosophic thought, or a wise piece of counsel to those in need. He was beloved by his many patients and his many friends. In masonic circles he was well known as a past master of Lord Stanley Lodge and a provincial officer. He was an excellent after-dinner speaker with a great sense of humour, and took great delight in music. He was for many years a justice of the peace, and served as chairman of the Manchester Division of the Association in 1934-5, of which Division he was a member since 1902. His passing leaves many sad hearts and all mourn the loss of a man devoted to all that is good in life. He leaves a widow and two daughters.

Dr. THOMAS ST. CLAIR SMITH died on Dec. 6 at the age of 71 at Chipping Norton, Oxfordshire, where he had lived for many years. He was educated at St. Paul's School, Cambridge University, and St. George's Hospital, where he took the M.B., B.Chir. in 1903. While still a schoolboy he came into prominence as a sprinter, and astonished London by beating A. R. Downer, the reigning sprint champion, in a 220-yards race at Stamford Bridge off a low handicap mark. It was expected that he would qualify for a blue at Cambridge, but he never did so, partly because he stopped growing earlier than most boys do but even more because he would not take his training sufficiently seriously. His slight, short, wiry figure was in fact more that of the typical long-distance runner than that of a sprint-racer. His interests were entirely those of a countryman, and he never practised in a town, where from a purely worldly point of view he might have attained greater material success. He served in the R.A.M.C. in 1914-18, and retired from practice some years ago.

## The Services

Major-General R. W. Galloway, C.B., C.B.E., D.S.O., late R.A.M.C., has been appointed Honorary Surgeon to the King, in succession to Major-General W. C. Hartgill, C.B., O.B.E., M.C., late R.A.M.C., retired.

Major-General R. E. Barnsley, C.B., M.C., late R.A.M.C., has been appointed Colonel Commandant of the R.A.M.C. in succession to Major-General O. Ievers, C.B., D.S.O., late R.A.M.C., whose tenure of appointment has expired.

Colonels W. H. Kerr, T.D., and J. P. Clarke, T.D., and Brigadier W. Anderson, O.B.E., R.A.M.C., T.A., have been appointed Honorary Colonels to No. 3 (Western) General Hospital, No. 8 (Western) General Hospital, and No. 5 (Scottish) General Hospital, respectively.

### DEATHS IN THE SERVICES

Capt. JAMES ARKLESS, R.A.M.C., who qualified in 1945 and was later house-surgeon at the Tynemouth Victoria Jubilee Infirmary, died suddenly in North-West Germany, on Dec. 6.

A correspondent writes: One of the younger medical officers on the staff of a military hospital, he was the most popular man in the unit. Some of us have known him only under the difficult circumstances which are faced by an Army of Occupation, but as a result of those very difficulties we have known him at his best, for here his gifts of generous living had ample scope. His death from acute anaphylactic shock following an injection of anti-tetanic serum after he sustained a minor injury will present his family and closest friends with the question why one so young, so full of promise, and so charged with vitality should so abruptly reach life's end.

## Medical Notes in Parliament

### Medical Practitioners and Pharmacists Bill

In the Committee stage on Dec. 9 Clauses 1 and 2 were ordered to stand part of the Bill. On Clause 3 Mr. JOHN EDWARDS moved amendments to meet the case of alien doctors who, although they had not served in H.M. Forces, had given valuable service in some civilian medical capacity overseas. The date "Sept. 1, 1939" was inserted to ensure that only service during the war period should count. One part of the amendments provided for aliens who served with the Red Cross, the Friends' Ambulance Unit, and similar bodies in co-operation with the British Forces. Another part was intended to cover alien doctors employed as civilians who had looked after the medical welfare of prisoners of war, internees, and the civilian population generally in British territories overseas which had been the scene of military operations or which had been in enemy occupation. Mr. Edwards said the limitation which applied to doctors who settled in the United Kingdom would apply also to these people.

Mr. WALTER ELLIOT said the Opposition did not propose to offer any objection to these amendments. Nevertheless they widened the Bill to some extent and he asked whether the Minister had had consultations on this point with the professional organizations concerned. These organizations thought they had been generous in opening the *Register* to a considerable number of new entrants.

Mr. EDWARDS said that he was not aware of any difficulty with the professional organizations on this point. There might seem to be a widening, but relatively few people would be covered and the House ought not to leave out persons who had rendered meritorious service but who did not happen to be in the Forces.

Mr. ELLIOT said he thought the general purpose of the amendment, which was to ensure that people were not left out because of some technical objection, was sound. The liberality of the learned profession of medicine was displayed in its acceptance of this addition to the already considerable opening of the *Register* to which this Bill gave effect.

The amendments proposed by Mr. Edwards were then accepted. On the motion that the Clause as amended stand part of the Bill, Mr. GALLACHER asked whether an American osteopath and other types outside the recognized medical fraternity in this country could be included for the purposes of the Act. Mr. HOUSE asked a similar question about an American naturopath. Mr. EDWARDS replied that the answer was "No."

The Clause as amended was then ordered to stand part of the Bill. On Clause 8 Mr. J. EDWARDS moved to insert a provision that where a direction for registration under this section was given the General Medical Council might include a direction that the right to registration should be subject to payment of a fee not greater than the fee for registration as Commonwealth practitioners or as foreign practitioners under Section 11 or 12 of the Medical Act, 1886. Mr. Edwards said it would be invidious that distinguished visitors who came here for our benefit and not primarily for their own should pay a fee, but the postgraduate student was here for his own advantage and in such cases a fee could be justified. Work would be entailed in following the movements of such a student. It had therefore been decided to give the Council power in such cases to charge a fee not exceeding the present £5, and to leave the Council free to reduce or to waive the fee if it thought fit.

Mr. GALLACHER suggested that after the passage of this amendment medical M.P.s should cease to object to the demand of the trade unions that those who came into an industry should become members of the union and pay their dues.

Mr. ELLIOT said the House was not dealing with the British Medical Association but the General Medical Council, a statutory body over which the medical profession had no rights at all.

The amendment proposed was agreed to, and, on the motion that the Clause as amended stand part of the Bill, Mr. SOMERVILLE HASTINGS said the less able the doctors who came to study our methods were the more anxious they were to take home to their own country some demonstration of their ability. If they could carry home a certificate that they had acted as house-surgeon in a British hospital they would be greatly pleased, and their patients would be much impressed. He realized the desirability of distinguished doctors coming here, but if the smaller fry were allowed to treat in our hospitals cases which they were not allowed to treat outside, it was a bit dangerous. He wished to see the Clause tightened up if possible. As it stood it left the public in hospital at the mercy

of people less well qualified and less able to treat disease than those who qualified in the ordinary way here.

The Clause as amended was ordered to stand part of the Bill and the remaining Clauses were approved without amendments. The Bill as amended then passed through Report Stage and Third Reading without further discussion.

On Dec. 16 the House of Lords considered the amendments made by the House of Commons in the Medical Practitioners and Pharmacists Bill. Lord HENDERSON, for the Government, said these amendments were simple and straightforward. The scope of the provisions had been carefully limited and had evoked no objections from the medical profession, who had been kept informed of what was now proposed.

The House concurred in the amendments to Clause 3 and also with one in Clause 8 giving the General Medical Council power to charge a registration fee, not exceeding the normal fee, for postgraduate students.

### Food Stocks

On Dec. 12 Mrs. AYTON GOULD expressed concern about the cuts in food which she said were impending in the New Year. She urged the Government to use up existing stocks, particularly of sugar and bacon, in January and February when the vitality of the people was at its lowest and mortality was highest. She pointed out that it was impossible to feed at school more than half the children of school age.

Lord WINTERTON asked for a medical examination of the weight and general condition of those children who received school meals and of those who did not.

Mrs. CASTLE said steps should be taken to get the maximum amount of vegetables into the homes.

Dr. EDITH SUMMERSKILL said the suggestion that the nation should now eat into its stocks might emanate from an imprudent housewife, and would not leave enough at the end of the rationing period. While shortages continued the Ministry of Food made special arrangements to safeguard the vulnerable groups of the population and had given them extra rations. The Ministry conducted special surveys each month so that any deterioration in the condition of those groups was brought to its notice immediately. In co-operation with the Ministry of Health and its Standing Committees, the Ministry of Food continued to observe the condition of the people of the country. Medical inspectors of schools co-operated with it.

### Advance Information

MR. ASTERLEY JONES asked the Minister of Health on Dec. 19 if his attention had been drawn to premature disclosure in the Press of an account of the proceedings in his recent discussions with the doctors. (See annotation entitled "Advance Information" in the *Journal* of Dec. 20, p. 1005.)

MR. BEVAN, in a written Parliamentary reply, stated: Yes, Sir. In certain newspapers I have been accused of premature disclosure of matters which were discussed by me with the Negotiating Committee of the profession and which it was agreed should not be published before to-day. The discussions in question took place between some 40 representatives of the profession or officials of the British Medical Association, the Secretary of State for Scotland, myself, and some officers. So far as my right hon. friend, myself, and our officers are concerned, I can state categorically that no disclosure of any kind has been made or condoned. The motives underlying these statements can only have been to embitter my relations with a profession whose co-operation I am sincerely seeking. Fortunately, I do not believe that many in the profession are actuated by such motives.

**Surgical Boots.**—Mr. BELCHER said on Dec. 16 that he was aware of the difficulties in obtaining surgical boots. Special assistance had always been given to surgical boot makers whose work was held up by lack of materials. The Board of Trade was introducing a further scheme to enable types of leather normally reserved for export to be bought for surgical boots. There had been some success in finding European volunteer workers for surgical boot making.

**N.H.S. Administration.**—Col. STODDART-SCOTT inquired on Dec. 11 whether the Government's decision with regard to Ministers' replies to Parliamentary inquiries about nationalized industries also referred to nationalized hospitals and the specialist and other services administered by Regional Hospital Boards. (This decision ruled out Parliamentary questions on detailed administration.) Mr. BEVAN replied: "No, sir." He added that the Health Ministers would be answerable for these services and therefore for their administration by the local or regional bodies set up for the purpose. But it was to be hoped that the proper responsibilities of those bodies would not be diminished by too many inquiries on detailed day-to-day matters unless some point of general importance was involved.

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE

The Raymond Horton-Smith Prize for 1946-7 has been awarded to M. G. P. Stoker, M.D., for his thesis on a laboratory investigation of the Rickettsial diseases of India. J. F. Stokes, M.D., was *proxime accessit* for his thesis on the terminal stages of infective hepatitis.

Titles of degrees were conferred by diploma on the following members of Girton and Newnham Colleges during November: L. A. Farquharson, M.B., B.Chir., J. K. Goodacre, M.B., B.Chir., G. F. Jacob, M.B., B.Chir., I. Kane, B.A., M.B., B.Chir., P. D. Kilner, M.B., B.Chir., and R. M. Licence, M.B., B.Chir.

On Dec. 6 the degree of M.B., B.Chir. was conferred (by proxy) upon G. A. Bracewell.

The following candidates have been approved at the examination indicated:

FINAL M.B.—*Part I (Surgery, Midwifery and Gynaecology)*: N. Allsup, V. E. Amassian, J. C. Barker, G. P. Blanshard, D. G. Bonham, M. D. M. Bowen, P. H. Brighi, I. W. Broomhead, R. W. Brown, D. T. Cox, E. H. Eason, W. J. D. Eberlie, C. P. E. Elliott-Binns, P. Fehrsen, D. V. G. Feltham, J. E. Forster, R. A. Fox-Linton, I. W. de G. Gregory, R. H. Griffith, J. L. Hansell, I. Henderson, C. Q. Henriques, J. L. Hine, M. Honey, J. B. Howells, P. B. Hughes, P. V. Ingram, G. W. C. Johnson, D. G. Julian, E. A. Kauffmann, W. I. N. Kessel, W. M. Keynes, H. A. Lomax, I. S. Longmuir, P. H. Lord, J. A. MacDougall, A. G. Mackenzie, B. K. Madden, J. Mander, H. Middleton, P. F. D. Naylor, G. W. Page, C. M. B. Pare, K. N. J. Pocock, A. Polak, S. Powell, T. M. Robinson, R. A. Ryan, F. R. Ryle, J. E. S. Scott, R. T. Sears, L. Sefton, J. M. L. Shearer, R. S. Smith, P. W. Sole, E. F. Southill, W. F. W. Southwood, D. I. Storey, C. H. Talbot, R. G. O. Taylor, J. P. D. Thomas, K. R. Wallace, W. R. Walsh, J. C. Wardill, D. B. J. Wardle, G. H. Warrick, A. L. Wells, H. I. Williams. *Women*: C. B. Alvey, J. Bean, E. M. Bennett, R. M. Bower, Mrs. K. H. Cohen, P. M. Glasspole, M. H. Jerwood, Mrs. L. M. Rochelle, Mrs. H. B. Roxburgh.

### UNIVERSITY OF LONDON

The British Postgraduate Medical Federation of the University has awarded Postgraduate Travelling Fellowships for 1947, tenable for one year, to S. C. Gold, M.B., B.Chir., M.R.C.P., of St. George's Hospital (Dermatology, Switzerland and U.S.A.); A. Hargreaves, M.B., B.Chir., of University College Hospital (Dermatology, Switzerland and U.S.A.); R. Shackman, F.R.C.S., of the British Postgraduate Medical School (Surgery, U.S.A.); and D. B. Taylor, M.B., B.Ch., of King's College (Pharmacology, U.S.A.).

### UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

FINAL M.B., Ch.B.—Mary K. Astin, A. Coady, M. B. Edwards, D. D. Hilton, R. A. Kershaw, A. Kinsey, C. I. Moss, R. Ormerod, J. F. Parry, F. A. Rainford, O. R. W. Sejrup, B. Stone, Margaret E. Thorp, R. J. A. Webb, H. W. Wilson, P. Wolf, D. H. Wright. *Part I*: Helen E. Mafr, K. D. Pinson, A. D. Robinson, A. M. Sellars, H. L. Wolfe, D. H. Yates.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—*Part II*: G. Christie, F. Howarth, Mrs Helen E. Smith.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

At an ordinary meeting of the Council of the College held on Dec. 11, with Sir Alfred Webb-Johnson, Bt., President, in the chair, the following were elected to the Fellowship in Dental Surgery: Mr. H. Chapman, Mr. L. C. Attkins, Mr. W. B. Grandison, Mr. Bowdler Henry, Prof. H. H. Stones, Mr. R. Weaver, Mr. C. W. Roberts, Mr. H. G. Watkin, Mr. A. G. Allen, Mr. J. F. Pilbeam, Miss Eleanor M. Knowles, Mr. G. H. Leatherman, Prof. G. L. Roberts, Mr. R. Cocker, Mr. P. J. Stoy, Mr. B. W. Fickling, and Prof. E. L. Sheridan.

It was reported that the late Mr. Frédéric F. Burghard, C.B., M.D., M.S., F.R.C.S., had left a bequest to the College for the endowment of research scholarships. The Council gratefully received from Mr. H. B. Willett the gift of a portrait of John Abernethy.

The following hospitals were recognized in respect of the resident surgical posts required of candidates for the Final Fellowship examination: Whipp's Cross Hospital, London, E. (the two house-surgeons); Ingham Infirmary, South Shields (resident surgical officer); Taunton and Somerset Hospital (three house-surgeons, for the period of one year in the first instance).

Sir Hugh Cairns, K.B.E., D.M., F.R.C.S., Nuffield Professor of Surgery in the University of Oxford, left England on Dec. 23 for a three-months visit to Australia and New Zealand as the first of his Arthur Sims Travelling Professor. He will deliver lectures, make contact with leading medical scientists, and take part in research and postgraduate teaching. Arrangements are being made for

Sir Hugh Cairns to visit the principal medical centres of South Africa in the summer of 1948. It is confidently hoped that the institution of this Travelling Professorship will not only do much to stimulate the development of medical science for the benefit of mankind but that it will also prove a further valuable link between the Nations of the Commonwealth.

Diplomas of Membership were granted to R. G. Donaldson (Westminster), and B. C. Luker and G. G. Parsons (St. Thomas's).

Diplomas in Child Health were granted, jointly with the Royal College of Physicians of London, to M. B. Gamat and A. D. M. Jackson.

Diplomas of Fellowship were granted to the following successful candidates:

W. A. D. Drummond, D. D. Cranna, J. R. St. G. Stead, H. A. Pearce, N. E. James, B. S. S. Acharya, I. Jacobson, C. M. Squire, A. D. Bateman, R. W. Gunderson, J. N. M. Parry, G. H. A. Simmons, W. W. Wilson, N. L. Crabtree, J. C. A. Innes, A. J. S. Bell Tawse, R. C. Fuller, W. McC. Scott, H. D. S. Vellacott, R. P. M. Miles, B. H. Price, B. C. Rowlands, H. P. Guerrier, D. N. Fuller, H. O. Jones, B. W. Wells, R. C. Connolly, M. H. Wostenholm, G. A. Barclay, J. F. North, R. P. Warren, J. F. R. Bentley, J. F. N. C. Ward-McQuaid, W. E. S. Bain, J. R. Thompson, S. M. Chris, S. R. Mawson, P. P. Rickham, J. Fry, F. I. Tovey, I. Hivazi, F. V. Stonham, C. D. Clark, M. T. Greig, L. N. Bartholomew, J. R. Grimoldby, J. Burke, K. B. Burnside, N. C. Hughes, A. C. R. Sharp, R. E. Gibbins, K. N. McNamara, H. M. J. Windsor, K. R. Archer, J. A. Key, R. F. Lowe, E. M. Nanson, D. P. Sansford, P. R. H. Slade, A. W. Sutherland, R. C. Willis, S. Acharya, J. R. Addison, D. Aiken, T. J. Butler, J. P. Fleming, D. McD. Kenny, K. N. Morris, B. Mukopadhyaya, Jean M. Sandel, S. Banerjee, A. A. Brown, R. P. Jepson, M. Laird, T. F. Miller, I. Barnat, A. Hulme, L. I. W. Cox, K. N. Dastur, A. W. Fowler, I. Macnab, J. B. Parikh, A. E. Carter, F. G. Westgate.

### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At the annual meeting of the College held on Dec. 4 Dr. W. D. D. Small, C.B.E., was elected President, and Dr. R. Cranston Low, Prof. L. S. P. Davidson, Drs. J. D. S. Cameron, C.B.E., H. I. Wallace, and I. G. W. Hill, C.B.E., and Sir David K. Henderson were elected to form the Council for the ensuing year. Sir David K. Henderson was nominated Vice-President. Drs. R. Cranston Low and A. Ninian Bruce were elected Representatives of the College on the Board of Managers of the Royal Infirmary of Edinburgh for the ensuing year.

### ROYAL COLLEGE OF SURGEONS IN IRELAND

The following candidates were successful in the Fellowship examinations: D. P. Beckett, R. E. Fenelon, R. S. Murray, J. R. McElroy.

The Fellowship was conferred on Dr. John Bunting on Dec. 12

### ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of Council held in the College House on Nov. 22, with the President, Mr. William Gilliat, in the chair, the following were formally admitted to Membership of the College: Robert John McConnell Jamieson, Joan Edith Warner Mackie, Stephen Parlee (*in absentia*), and Ada Sau Haan Wong (*in absentia*).

The following candidates have satisfied the examiners for the Diploma in Obstetrics:

K. D. G. Abbott, E. A. J. Alment, G. J. Amiel, G. Anderton, J. K. Armstrong, W. C. Astley, Winifred N. Backhouse, A. B. Backus, Henrietta E. Banting, C. P. Bennett, W. R. Bodenham, C. C. Bowley, M. Bruser, C. J. Champ, J. S. L'A. Chesshire, S. N. Cole, J. Colquhoun, Janet E. V. Copland, J. M. G. Costello, H. H. Crabb, R. Crawford, R. C. Cummin, D. V. Cummins, Nora C. Curran, R. Cutts, C. H. De Boer, N. S. Devi, C. J. Dewhurst, L. W. D. Drabble, W. J. Friend, R. W. Grayburn, E. G. Hall, A. Hanton, S. L. Hetherington, N. M. O'C. Driscoll, V. Drosso, J. G. Dumoulin, A. Eckford, D. F. Edmiston, M. S. Ellensweig, J. Eskell, J. Firth, J. H. Fisher, G. H. Flack, H. D. Freeth, H. J. Friend, R. W. Grayburn, E. G. Hall, A. Hanton, S. L. Hetherington, N. M. O'C. Hewett, G. E. Hicks, R. Hodgkinson, E. J. Holloway, D. R. Hughes, A. Hunter, R. W. Hutchinson, C. G. Irwin, S. B. Jahan, E. W. Jeyaratnam, A. Joffe, F. W. Johnson, E. P. Jones, E. W. Jones, R. A. S. Keighley, P. G. S. Kennedy, R. W. Kennon, P. M. Kerr, J. E. Kerton, B. T. Kiehl, Muriel G. King, G. Kirtane, W. H. Laird, J. L. Lawrence, R. P. Lawrie, J. B. Lawson, J. McL. Lees, M. H. Lloyd, Mary Love, H. McColl, Kathleen A. McDonald, R. McIntosh, Muriel MacKenzie, A. G. MacLeod, J. C. MacWilliams, A. S. Majury, H. N. Mansfield, Anna Mathan, T. K. Maurice, T. D. F. Money, Ivy M. Morgans, M. F. Morton, W. H. Oesterlein, G. C. Pattanayak, J. H. Patterson, P. C. A. Posford, G. Quane, W. J. Ramsay, E. B. Rayner, D. H. Read, D. D. Li. Reet, Jocelyn G. Reynolds, H. Roberts, P. S. Robinson, E. S. Rogers, Monica H. Roper, J. Rushton, G. T. Rutherford, Helen Samson, Mary A. Saunders, P. G. Seed, Elizabeth S. M. Sherrard, D. W. Shields, Irene M. S. Sloper, L. Smalley, A. A. Smith, E. M. Southern, Elizabeth M. Stokes, A. Taylor, A. P. Walker, J. Watson, Joyce Watson, A. E. B. de Courcy Wheeler, J. Wilbush, Mary L. Williams, R. B. Wilson, C. H. F. Wood, Esme M. Wren, R. B. Wright.

### FACULTY OF RADIOLOGISTS

At the recent examination for the Fellowship of the Faculty of Radiologists the following candidates satisfied the Fellowship Board: *Radiodiagnosis*, J. E. Blewett, M.D., D.M.R., W. J. Latham, M.R.C.S., L.R.C.P., D.M.R.D., S. A. Maddocks, M.R.C.S., L.R.C.P., D.M.R.E. *Radiotherapy*, E. Millington, F.R.C.S.Ed., D.M.R.

No. 49

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Dec. 6.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis

The chart here reproduced illustrates the course of the poliomyelitis epidemic from the week ending May 31 (3 cases) to the week ending Dec. 6 (70 cases). It shows well the steep rise in the number of notifications from the week ending July 12 (110 cases) to the week ending Aug. 16 (646 cases), followed, after a slight fall, by the peak figure of 662 for the week ending Sept. 6. There has since been a steady decline in the number of notifications. The total number of cases notified during the 28 weeks was 8,157. This is the uncorrected figure, and it will be recalled that the 6,192 notifications for the September quarter have now been corrected to 5,077 (Dec. 13, p. 982). In the opening pages of this issue of the *Journal* there are three articles on different aspects of poliomyelitis, and reference should also be made to a leading article at p. 1038.

## Discussion of Table

In *England and Wales* increases were recorded in the notifications of scarlet fever 262, measles 27, and dysentery 16. There were decreases in the incidence of acute pneumonia 37, poliomyelitis 33, whooping-cough 25, and diphtheria 11.

A rise in the incidence of scarlet fever was reported from all areas, but the increase was largest in the northern section of the country. There was a continuing rise in the South in the notifications of measles, and the largest increase was Northamptonshire 121; in the North there was a fall, and the largest decreases were Glamorganshire 89, Yorkshire West Riding 46, Durham 44, and Cumberland 41. Relatively small fluctuations were reported in the local trends of whooping-cough. The only large variation in the returns of diphtheria was a decrease of 15 in Lancashire.

Seven of the 8 cases of paratyphoid fever were notified in Yorkshire West Riding, Kirkburton U.D., where 7 cases were also notified in the preceding week. The chief centres of dysentery were Lancashire 24 (Manchester C.B. 11, Liverpool C.B. 8); Warwickshire 10 (Royal Leamington Spa M.B. 7); and Glamorganshire 9 (Cardiff C.B. 6). The largest returns of poliomyelitis during the week were Middlesex 8 and Lancashire 8.

In *Scotland* increases were recorded in the notifications of measles 34 and acute primary pneumonia 31; there was a decrease in the notifications of diphtheria 14.

In *Eire* increases occurred in the incidence of whooping-cough 20, measles 14, and diphtheria 8. The notifications of diarrhoea and enteritis decreased by 14. The increase in cases of measles was contributed by outbreaks in Dublin, Rathdown No. 1 R.D. 40, and Galway, Ballinasloe R.D. 21. The largest increase in the incidence of whooping-cough was 10, in Waterford C.B. An outbreak of diphtheria involving 8 persons was reported from Meath, Navan R.D.

In *Northern Ireland* only one case of measles was notified, a decrease of 22, while the notifications of scarlet fever increased from 47 to 59.

## Quarterly Returns for Scotland

Births during the September quarter were equivalent to a rate of 20.8 per 1,000, which was 2.7 above the average of the corresponding quarter of the five preceding years. The infant mortality was 50 per 1,000 registered live births, being 5 above the figure for the September quarter of 1946 but 4 below the five years' average. Stillbirths were equivalent to a rate of 31 per 1,000 total births. Maternal mortality was 2.0 per 1,000 live births and was 0.8 below the five years' average. The general death rate was 10.6 per 1,000, being 0.8 below the five years' average. Deaths from epidemic diseases included 27 from whooping-cough, 7 from measles, 5 from diphtheria, 9 from cerebrospinal fever, and 8 from influenza. The death rate from all forms of tuberculosis was 69 per 100,000, and

from respiratory tuberculosis 55. The death rate for all forms of tuberculosis was 3 lower than the five years' average; the death rate from respiratory tuberculosis was unaltered.

### Annual Report for Scotland, 1945

During 1945 Scotland had the lowest birth rate ever recorded, the smallest number of deaths since 1861, and the greatest number of marriages, with the exception of 1940. The infant mortality was 56 per 1,000 births, the lowest rate ever recorded in Scotland. An analysis of the infant mortality by social class reveals differences. It had been expected that the improved dietaries for pregnant women which had virtually levelled social class differences in diet would remove the difference in infant mortality between the social classes. This had not occurred, but the opposite has been found for stillbirths. In 1939 there was very little difference in the stillbirth rate of the five social classes, but in 1945 the rate varied from 20.9 per 1,000 for the wives of professional men to 39.1 among the wives of unskilled labourers.

## Medical News

### Institute of Social Psychiatry

The Institute of Social Psychiatry met on Nov. 15, under the chairmanship of Dr. Noel Harris, to discuss therapeutic social clubs. About 50 psychiatrists and psychiatric social workers were present. The next meeting will be held on Jan. 14, 1948. All superintendents and medical officers in charge of out-patients, who have started or who are interested to start a club, are invited to get in touch with the Institute of Social Psychiatry at 7, Fellows Road, London, N.W.3.

### St. John's Hospital for Diseases of the Skin

An appointment system for all patients will start at St. John's Hospital for Diseases of the Skin (5, Lisle Street, Leicester Square, London, W.C.) on Jan. 1, 1948.

### New Rules Governing Poisons

The Poisons (Amendment) Rules 1947 (S.R. & O. 1947 No. 2555) will come into operation on Jan. 1, 1948. They provide for some relaxation in the restrictions at present imposed on the sale of nicotine dusts containing not more than 4% of the poison and of ointments and dressings containing sulphonamides. It will no longer be necessary for an entry to be made in the poison book in respect of any sale of nicotine dusts within the specified limit. It will be lawful to sell ointments and dressings containing sulphonamides without the prescription of a doctor, but these articles remain subject to the provisions of Section 18 (2) of the Pharmacy and Poisons Act; therefore sales must still be entered in the poisons book and the purchaser's signature obtained. It will no longer be necessary for the "dose to be taken" to be included in a prescription directing the supply of any Fourth Schedule poison which is to be used for external treatment only.

The remaining Rules have the effect of making permanent certain provisional Rules made during the war in respect of the sale of brucine in surgical spirit and of strychnine for the destruction of rats and moles. They do not make any change in the existing law other than to omit from the restrictions on the sale of strychnine any reference to the use of the poison by a purchaser after the transaction has been completed (Rule 29A of the Poisons Rules 1935-46).

Copies of the Rules may be bought (price 1d. net) from H.M. Stationery Office

### Will

Dr. Sydney Arthur Monckton Copeman, F.R.S., who died on April 11, left £71,296.

## COMING EVENTS

### Family Life

The Family Relations Group is organizing a conference on "Education for Family Life" to be held on Jan. 5-6, 1948, at King's College, Strand, London, W.C.2. Further details and application forms may be obtained from Mr. Cyril Bibby, Family Relations Group, 69, Eccleston Square, London, S.W.1.

### Medical Society of the L.C.C. Service

The annual general meeting of the Medical Society of the L.C.C. Service will be held at County Hall, Westminster Bridge, London, S.E., on Wednesday, Jan. 7, 1948, at 4.15 p.m., when the retiring president, Dr. R. C. Harkness, will deliver his presidential address on "Medical Staff Problems in Municipal Hospitals, Past, Present, and Future."

### Genetics

The 8th International Congress of Genetics will be held in Stockholm on July 7-14, 1948.

### Congress of Psychology

The International Congress of Psychology will be held at Edinburgh on July 23-29, 1948, under the presidency of Emeritus Professor James Drever, whose son, Prof. James Drever, of the University of Edinburgh, is arranging the programme. The secretary is Prof. Godfrey Thomson.

## APPOINTMENTS

The Royal Society has appointed Dr. K. Bailey, of the Biochemical Laboratory, Cambridge, to an Alan Johnston, Lawrence and Mosley Research Fellowship into the problems of human and animal health and diseases and the biological field related thereto. Dr. Bailey will work at the Biochemical Laboratory in Cambridge on the proteins of muscle fibril. The Society has also appointed Dr. G. S. Dawes, of Worcester College, Oxford, to a Foulerton Research Fellowship in Medicine. Dr. Dawes will work at the Department of Pharmacology, Oxford, on the left ventricle reflex. Both appointments date from Jan. 1, 1948.

Prof. D. F. Cappel, M.D., has been appointed chairman of the Technical Committee of the Scottish National Blood Transfusion Association in succession to the late Sir John Fraser, Bt., K.C.V.O., M.C., M.D., Ch.M., F.R.C.S.Ed.

BEETHAM, K. W., M.B., Ch.B., D.M.R.T., Radioltherapist, Hull Royal Infirmary.

FALLA, W. A. S., M.D., D.P.M., Medical Superintendent, Bracebridge Heath Mental Hospital, Lincoln.

## BIRTHS, MARRIAGES, AND DEATHS

### BIRTHS

Alderson.—On Dec. 5, 1947, in Newcastle, to Sybil J. Russell, M.B., B.S., wife of Bernard S. Alderson, M.B., B.S., a second son—Richard Russell.

Cormac.—On Dec. 6, 1947, at Stockport, to the wife of Dr. C. D. Cormac, a daughter.

Helm.—On Dec. 8, 1947, at 227, Whitegate Drive, Blackpool, to Kathleen Mary (née Walters), M.B., Ch.B., wife of Harold Helm, a daughter.

Law.—On Dec. 8, 1947, at London Hospital, E., to Beryl (née Dyson), wife of W. Alexander Law, O.B.E., F.R.C.S., 21, Chalmers Crescent, Highgate, N., a son—Bruce Alexander.

Leaming.—On Dec. 7, 1947, at Ruislip, Middlesex, to Barbara (née Todd), wife of Dr. H. Leslie Leaming, a sister for Douglas—Mary Jane.

Russell.—On Dec. 6, 1947, at Clovelly, Sandown, Isle of Wight, to Hazel (née Webster), wife of Dr. A. McC. Russell, a daughter.

### DEATHS

Adam.—On Dec. 10, 1947, at 2, Avonmore Mansions, London, W., John Ewing Adam, M.D., F.R.C.S.Ed.; aged 78.

Arkless.—On Dec. 6, 1947, in N.W. Germany, James Arkless, M.B., Captain, R.A.M.C.

Brooks.—On Dec. 11, 1947, Ivan Ernest Brooks, M.B., Ch.B., of Earlsfield, Darwen, aged 41.

Carwardine.—On Dec. 9, 1947, at Hindhead, Thomas Carwardine, M.S., F.R.C.S.

Coe.—On Dec. 13, 1947, Dennis Henry Coe, M.R.C.S., L.R.C.P., of King's College Hospital.

Cooper.—On Dec. 13, 1947, at 6, Holly Place, London, N.W., Henry Cooper, D.S.O., M.R.C.S., L.R.C.P., Group Captain, R.A.F.

Curphy.—On Dec. 12, 1947, at Lansdown Nursing Home, Bath, Elizabeth Curphy, M.R.C.S., L.R.C.P.

Dowling.—On Dec. 15, 1947, in Preston, Lancs, Edward Dowling, M.D.

Findlay.—On Dec. 13, 1947, at 16, Murrayfield Drive, Edinburgh, James Findlay, M.B., Ch.B., Lieutenant-Colonel, I.M.S., retired.

Freeth.—On Dec. 16, 1947, at 134, Cheam Road, Cheam, Surrey, Charles Mead, Maidenhead, aged 57.

Gilmour.—On Dec. 10, 1947, at Queen Elizabeth Hospital, Birmingham, Edward Raymond Gilmour, M.D., D.P.H., D.T.M., Medical Officer of Health, Leamington Spa.

Gunn.—On Dec. 14, 1947, at 234, Manchester Road, Audenshaw, nr. Manchester, William Gillespie Bryson Gunn, M.B., Ch.B.

Johnston.—On Dec. 15, 1947, at 19, West Avenue, Bryn Newydd, Prestatyn, Francis Johnston, M.D.

Marriott.—On Dec. 10, 1947, at Royal Masonic Hospital, William Marriott, M.R.C.S., L.R.C.P.

Maxwell.—On Dec. 13, 1947, Aymer Douglas Maxwell, M.C., M.B., Ch.B., aged 58.

Milligan.—On Dec. 11, 1947, at The Firs, Guildford, James Knowles Milligan, M.R.C.S., L.R.C.P., aged 65.

Moody.—On Dec. 11, 1947, William Ernest Moody, M.R.C.S., L.R.C.P., aged 67.

Perrott.—On Dec. 10, 1947, at 140, Clayhall Avenue, Ilford, Essex, George Francis Donaldson Perrott, M.R.C.S., L.R.C.P.

Poston.—On Dec. 11, 1947, Sallie, the beloved wife of Henry Poston, M.Ch., F.R.C.S.Ed., of "Malone," Manor Road, Cheddle Hulme, Cheshire.

Seecombe.—On Dec. 16, 1947, at 134, Cheam Road, Cheam, Surrey, Charles William Seecombe, M.R.C.S., L.R.C.P.

Smith.—On Nov. 13, 1947, at Melbourne, Australia, Julian Augustus Romaine Smith, M.D.

Spilsbury.—On Dec. 17, 1947, Sir Bernard Henry Spilsbury, M.B., B.Ch., F.R.C.P.

Stewart.—On Dec. 8, 1947, at The Elms, Gerrards Cross, Bucks, Rothway Charles Stewart, M.R.C.S.

Woolley.—On Dec. 16, 1947, at 8, Somerhill Road, Hove, Jasper Maxwell Woolley, M.D., Lieutenant-Colonel, I.M.S., retired.

## Any Questions?

### Protection against Colds

**Q.**—Has it ever been demonstrated that either vitamin supplements or oral vaccines give any protection against colds and influenza to workers in factories and offices?

**A.**—There is no satisfactory objective evidence that vitamin supplements, beyond what is required for a properly balanced diet, or "anticatarrhal" vaccines given orally or by injection, have any prophylactic value against the common cold. (For a review of the evidence see Browning, *Control of Common Fevers*, 1944.) If, on the other hand, there is evidence of a deficiency in any vitamin in a community, resistance to infection by the virus of the common cold and, more particularly, to secondary bacterial infection might be lowered; in which case vitamin supplements might serve a useful purpose. Thus, cod-liver oil or concentrates supplying vitamins A and D, and orange juice or its equivalent containing vitamin C, are given to babies and young children, whose requirements are relatively greater than those of adults. The prophylactic injection of vaccines containing influenza virus A and B has in controlled trials given encouraging results, although precautions may have to be taken to ensure that the vaccine contains the particular serological type of virus that is prevalent in the community at risk.

### Circumcision in Small Boys

**Q.**—In the case of boys aged 3 to 5 years, what is the accepted view on the advisability of operation where a long but retractable foreskin causes no symptoms or difficulty?

**A.**—There has been a reaction against indiscriminate circumcision. If the prepuce of a small boy is easily retractable and is not causing any symptoms there is no reason why it should be removed. It is, of course, possible that at a later period in life it may predispose to balanitis and have to be removed, but to operate now on the assumption that this will necessarily be the case would be absurd.

From a psychological point of view, the effects of circumcision performed under proper conditions and with an anaesthetic correctly administered do not differ from those of any other procedure. But the operation done in infancy without an anaesthetic often predisposes to neurosis, especially if the infant is not given the immediate comfort and reassurance of the mother. It may be true that in the first few days of life an infant has no cutaneous sensation of pain, but the operation can nevertheless produce profound shock, both surgical and psychological, predisposing to anxiety states. This may show itself later in a horror of operation or the sight of blood. In other cases the tight prepuce is a cause of erection and masturbation, which leads the parent to seek the surgeon's aid. In such a case circumcision may be interpreted by the boy as punishment for his sexual feelings, and in turn lead to sexual repression and later to partial or complete impotence; or it may lead to anxiety whenever the sex feelings are even normally aroused. Once again reassurance and affection from the mother will help to counteract the idea of punishment and guilt. But these are only predisposing causes of an anxiety neurosis, which does not materialize unless later untoward experiences precipitate it. The presence of the mother both immediately before and after any operation in infancy may be a worry to the nurse, but her absence is a worry to the infant, filling it with separation anxiety. The question is: Which is considered the more important?

### Coitus during Pregnancy

**Q.**—(a) When should coitus be discontinued during a normal pregnancy? (b) Are there any dangers associated with intercourse during pregnancy? (c) Does the pregnant woman derive benefit from coitus, and is it possible for her to have an orgasm? (d) Should an abdominal support be worn during pregnancy?

**A.**—(a, b) Coitus should be avoided during the last month of pregnancy, and preferably during the last two or even three

months; otherwise there is a slight but appreciable risk of inducing premature labour and of introducing into the vagina pathogenic organisms capable of causing infection during and immediately after labour. During the first three months it may cause abortion, but the risk is so small that, providing there is no roughness, it can be disregarded in normal cases. When, however, there is a history of previous abortions coitus should be forbidden during the first trimester, and often during the whole of pregnancy. Any danger of injury to the softened and highly vascular vaginal walls is avoided by reasonable care.

(c) It is still disputed whether a woman at any time receives direct physical benefit from the act of intercourse or from the absorption of constituents of seminal fluid; the evidence is inconclusive. However, it is reasonable to regard it as beneficial for a woman to satisfy sex desire during pregnancy and to preserve marital harmony. The reactions of pregnant women to coitus vary; usually sex desire and the capacity for reaching orgasm are retained, but they may be less intense, especially in the later months.

(d) The majority of women carry their first pregnancy without discomfort and do not require any support. If they need support at all it is during the later weeks or months, when the support should be designed to grip the pelvic girdle and also to carry the weight of the uterus with a sling-like action rather than to constrict it. During second and subsequent pregnancies, however, when muscles and ligaments are less efficient, most women obtain a good deal of comfort from a maternity belt, and there is no reason why one should not be worn as soon as the need is felt. The necessity for a support should be assessed in each individual case, and is judged by the presence or absence of backache, sacro-iliac pain, and other muscular and ligamentary discomforts.

### Climate and Longevity

**Q.**—During a recent visit to Switzerland I gained the impression that there were fewer elderly people than in Great Britain. What is the average age in different countries? Where can I find information on the effects of climatic conditions on health?

**A.**—The average age of the population is never given in official statistics, but a comparison can be made by considering the proportion above a certain age. The following table illustrates the kind of variation that might be expected:

Year	Country	Percentage of Total Population	
		Aged Over 60	Aged 75 and Over
1941	Switzerland .. ..	13.1	2.5
1940	England and Wales ..	14.5	2.7
1941	Canada .. ..	10.2	2.1
1940	United States .. ..	10.4	2.0
1941	Éire .. ..	14.6	3.1
1940	Norway .. ..	12.6	3.2
1931	Spain .. ..	9.6	1.7

The three chief factors that influence the proportion of old people in the population are the birth rate, the death rate, and migration. There is a vast literature on climatic conditions and health. The easiest introduction would be to read papers given before the Section of Balneology and Climatology of the Royal Society of Medicine.

### Trichlorethylene Poisoning

**Q.**—In a factory where trichlorethylene is used for dry cleaning many of the workers complain of headaches and indigestion, and at least one has collapsed. Can death occur from inhalation of these fumes? Is trichlorethylene a cumulative poison, and are any permanent ill effects likely to result from constant inhalation? What is the first-aid treatment for collapse due to inhaling the fumes?

**A.**—The most striking characteristic of trichlorethylene is its acute narcotic action. Lehmann (*Arch. Hyg., Berl.*, 1911, 74, 1) says it is to chloroform as 1.7 to 1. Trichlorethylene is used industrially chiefly for metal degreasing and as a non-inflammable cleaning agent, but with proper control of working conditions there should be little or no fume from this narcotic.

### Secretariat

As has been stated above, the General Assembly left to the Council the question of the general organization of the secretariat. It considered, however, the desire expressed by the Latin American associations for the specific recognition of the Spanish culture in the Association's organization. They proposed the adoption of Spanish as a third official language, and the appointment of a Spanish Assistant Secretary, whom they offered to finance without cost to the Association. The Assembly adopted the first proposal. With regard to the second it recognized that, with the development of the Association's work, it might become desirable to appoint perhaps several assistant secretaries in different parts of the world. It therefore instructed the Council to include this matter in its consideration of the general organization of the secretariat and recommended for acceptance the kind offer of the Latin American associations.

### Proxy Voting in Assembly

The General Assembly referred to the Council for consideration a suggestion by Australia that provision should be made in the by-laws for voting by proxy in the General Assembly in order that far distant member associations, which might be unable to send delegates to a meeting of the General Assembly, should not thereby lose their voting power.

### War Crimes

After a discussion of the motions on the agenda by Denmark and Great Britain and the British memorandum relating to the attitude of the profession to war crimes, and after hearing statements by members of the Assembly and by a French medical victim of war crimes, the Assembly appointed a small committee to formulate a recommendation. The following report of the committee was subsequently adopted by the Assembly.

(i) That a report on crimes committed since 1933 by doctors and medical organizations in Germany and other countries and on this violation of the medical ethic be prepared and made available to doctors throughout the world.

(ii) That the World Medical Association solemnly condemns the crimes against human beings committed by certain members of the medical profession such as are described in the British memorandum.

(iii) That every doctor at the time of receiving his medical degree or diploma be required to subscribe to the following oath: "My first duty, above all other duties, written or unwritten, shall be to care to the best of my ability for any person who is entrusted or entrusts himself to me, to respect his moral liberty, to resist any ill treatment that may be inflicted on him, and, in this connexion, to refuse my consent to any authority that requires me to ill-treat. Whether my patient be my friend or my enemy, even in time of war or in internal disturbances, and whatever may be his race, his race, his party, his social class, his country, or his religion, my treatment and my respect for his human dignity will be unaffected by such factors."

(iv) That the World Medical Association endorse judicial action by which members of the medical profession who shared in war crimes are punished.

(v) That the World Medical Association request the German medical syndicates to make the following public declaration: (a) We, members of the German medical syndicate, are aware of the very large number of acts of cruelty committed both by individuals and collectively since 1933 in mental hospitals and in concentration camps and of the violation of the medical ethic. These acts have resulted in the death of some millions of people. A large number of our members have been implicated in these acts, either as instigators or as technical agents or as actual perpetrators. (b) We regret that the organized medical profession in Germany has not made any protest and has been content to ignore these acts, of which it could not have been unaware. (c) We undertake solemnly to condemn these crimes, to expel from our organization the criminals who committed them, and to remind all our members of the responsibility not only to life, but to human personality, dignity, and honour.

The Assembly instructed the Council to prepare a report incorporating these resolutions and also to take into consideration the following motion by the Netherlands:

That the Council be instructed to prepare a report on the collaboration of medical practitioners in the preparation of means of warfare.

### Matters Referred to Council

During the course of the meeting the General Assembly also referred the following matters to the Council for appropriate action or investigation and report:

(i) The general arrangements for the organization and publication of a bulletin or journal; (ii) the preparation of a report on the inquiry into the present position of the medical profession in relation to the State; (iii) the motions of Luxembourg, supported by Australia, recommending the preparation of a comparative statement of standards of training for the medical profession and conditions of registration, and of a comparative statement on the qualifications of specialists; (iv) the following motions by India:

(a) That the Council be requested to study and report on the question of the advertisement of cures and medicines in the lay press; (b) That the Council be requested to study and report on the question of unqualified and unauthorized medical practice;

(v) the preparation of Standing Orders to govern the procedure of meetings of the General Assembly; (vi) the appointment of auditors.

### Second Annual Meeting

The General Assembly decided to hold its 1948 meeting in Prague, the exact date being left to the Council to decide.

The General Assembly elected Dr. J. Stüchlick (Czechoslovakia) to preside over its Annual Meeting in 1948. He therefore becomes President-Elect for the year 1947-8. The General Assembly elected Dr. O. Leuch (Switzerland) as Treasurer of the Association for the period 1947-50.

### Council 1947-8

The General Assembly elected the first Council. Dr. Zahor (Czechoslovakia) and Dr. Glorieux (Belgium) having resigned after election, the Council for 1947-8 is composed as follows:—Ex-officio President: Prof. E. Marquis (France); President-Elect: Dr. J. Stüchlick (Czechoslovakia); Treasurer: Dr. O. Leuch (Switzerland); Chairman: Dr. T. C. Routley (Canada); Vice-Chairman: Dr. D. Knutson (Sweden); Drs. L. H. Bauer (U.S.A.), J. A. Bustamante (Cuba), P. Cibré (France), A. Hartwich (Australia), P. Z. King (China), J. A. Pridham (Great Britain), S. C. Sen (India), L. G. Tornel (Spain).

### Meeting of Council

At the conclusion of the General Assembly's proceedings the Council held its first meeting. Pending the establishment of a permanent office and the appointment of a full-time secretary, the Council appointed Dr. Charles Hill (Great Britain) as Honorary Secretary of the Association, with temporary headquarters at B.M.A. House, London.

The Council will consider the conditions of service to be offered for a full-time secretary and will make arrangements for receiving and considering applications for the appointment. It hopes that national medical associations will make known in their countries the offer of the appointment so that the field for the selection of the right person may be as wide as possible.

In accordance with the General Assembly's acceptance of the principle of the appointment of assistant secretaries, Dr. Bustamante, Secretary of the Pan-American Medical Confederation, was appointed Honorary Assistant Secretary for matters pertaining to the Latin American countries.

I hope this brief note will give a general idea of the results of the First Annual Meeting and of the work which the Association is to undertake during the coming year. The World Medical Association is now an established organization, and the Council trusts that every national medical organization will give it its full support.

CHARLES HILL  
Honorary Secretary

The Cheshire Protection of Practices Committee has issued a report summarizing its activities since the beginning of the war. The scheme resulted in a total of £98,418 being given to insurance practitioners serving with the Forces. The report pays tribute to the organizing ability of Mr. F. T. West, the Administrative Officer.

## TERMS OF COMPENSATION FOR OFFICERS OF THE INDIAN MEDICAL SERVICE

The Armed Forces Committee has had under consideration the terms of compensation for officers of the Indian Medical Service which were announced by the Government in a White Paper in April of this year. Following correspondence with the Commonwealth Relations Office on a number of points arising out of these terms, a deputation of representatives of the Committee met senior officials of the C.R.O. on Oct. 10 to discuss points of criticism and obscurity arising from the White Paper. The following is a summary of the representations made by the Committee, and the replies of the C.R.O.

### Basis of Compensation

The Committee commented on the fact that in the case of I.C.S. officers compensation was based on the completed years of service, whereas I.M.S. officers, in common with officers of the R.I.N. and I.A., have their compensation based on age. As there is considerable variation in the age of entry of officers of the I.M.S., the Committee recommended that where it can be shown that compensation based on age reacts to the disadvantage of an officer it should be possible for him to have his compensation based on years of service if the latter basis is more favourable.

The C.R.O. stated in reply that the difference in the bases of calculating compensation was due to the fact that in the I.C.S. the date of retirement was governed by years of service, whereas in the I.M.S. and other services it was governed by age. Moreover, while the age basis of compensation might in certain cases reduce compensation, it was equally true that if the years of service criterion were adopted for I.M.S. officers many would be penalized, particularly officers who entered the service late and had comparatively short service by the date of transfer of power. For example, an officer aged 39 with 9 years' service would have his compensation reduced from £6,000 to £3,375. It was further stated that at this stage it would be impossible to vary the basis of compensation.

### Officers Retired before Aug. 15, 1947

The Committee considered that there was some case for compensation for officers who, in view of the impending change of government in India, had secured other employment before the appointed day.

In reply it was stressed by the C.R.O. that entitlement to compensation does not exist except in the case of officers who were serving on the day when power was transferred. The only exception to this is the special provision announced by the Viceroy on April 30, 1947 (*vide* para. 10 of the White Paper). An officer of the I.M.S., civil or military as the case may be, who was specially released by the Viceroy, or granted the requisite certificate of compulsory retirement by the commander-in-chief, in advance of the appointed date, remains entitled to compensation and proportionate pension. If an officer had left India on leave pending retirement before Aug. 15, 1947, and claimed that his retirement was compulsory as a result of the acceleration of the Indianization of the Armed Forces, special consideration would be given to his case, and if his claim were accepted by the Viceroy or the commander-in-chief in India under the provisions referred to above he would be eligible for compensation. Save in these exceptional cases, the grant of compensation is not admissible to any officer who proceeded on leave preparatory to retirement before Aug. 15, 1947.

The Committee understands that as a result of the acceleration of the transfer of power the number of officers who took up other employment before the appointed day is very small. In fact only one such case has been brought to the Committee's notice, and in this case the officer concerned was aware that his acceptance of the appointment was likely to jeopardize his claim to compensation.

### Transfer of I.M.S. Officers to British Armed Services

The Committee sought further information about the C.R.O.'s intention regarding the transfer of I.M.S. officers to British

Armed Services. It was the Committee's view that this could be equitably effected only on the understanding that there would be no interference with the vested rights to the maximum career of the permanent officers in the Services accepting transfer of I.M.S. officers. If this view were accepted, it must follow that these Services could not offer the same opportunity for a maximum career for those I.M.S. officers who transferred to them. The Committee also wished to know if it was proposed that the Indian Government would accept responsibility for the payment to officers who transfer to British Services of the amount required to bring the pension earned in that Service up to the sum of the pension to which they would have been entitled in the I.M.S.

The C.R.O. stated in reply that I.M.S. officers with up to 20 years' service would be accepted by the three British Services, subject to individual suitability, and then only if they could be offered an adequate career. I.M.S. officers who were transferred would be treated in the same way as officers already serving. An officer who is transferred to the medical service of one of the U.K. Forces will receive one-quarter compensation and will have his reckonable service in the I.M.S. reckoned as service for British retired pay on eventual retirement. In addition, the special element of pension carried by service in India—i.e., the Indian element—will be assessed as on Aug. 15, 1947, or the date of the officer's transfer if before that date, and the amount due will be payable in addition to the pension granted under the regulations of his new Service. That is, he will receive on final retirement the pension or proportionate pension earned by service in the I.M.S. increased by subsequent service in the R.A.M.C. or other Service. For example, an I.M.S. officer aged 35 with 10 years of reckonable service in India will on transfer to the R.A.M.C. or other Service receive £1,125 (1/4 of £4,500), and, assuming that he finally retires from the British Service after a further service of 20 years, his pension on final retirement will consist of a pension based on 30 years' service in the R.A.M.C., etc., plus the specific Indian element of pension earned by 10 years' service in the I.M.S.

The C.R.O. regretted that no possibility could be seen of H.M. Government or the new Governments in India being prepared to accept liability for bringing the combined pension finally payable up to an amount for which an officer might have qualified had he continued to serve in the I.M.S. up to the date of final retirement.

### Transfer of I.M.S. Officers to H.M. Civil Services (including the Colonial Service)

The Committee drew attention to the dissatisfaction which had been expressed at the terms offered to officers who elect to be transferred to other Crown services, particularly the Colonial Medical Service. According to the White Paper such officers would forfeit compensation and receive only a resettlement grant of £500, while there was no guarantee that a transferred officer would enjoy seniority in his new service based on his service in the I.M.S. In the Committee's view officers transferred to Crown service should either (i) receive compensation in full, or (ii) receive full credit for all their service in the I.M.S. when their seniority and rate of contract pay in the new service are determined.

In reply the C.R.O. stated that so far as the Colonial Medical Service was concerned the point referred to in (ii) was already under examination, and they undertook to inform the Committee when a decision had been reached. With regard to pension, an officer appointed to a permanent pensionable post in one of H.M. Civil Services (including the Colonial Medical Services) will receive from the date of his retirement from Indian service the pension or proportionate pension earned by him during such service, to be drawn in addition to the pay of his new service, and he will begin to earn a separate pension in his new service from the date on which he joins for duty. Any officer who obtains an appointment under the Crown which is not permanent and pensionable, or who enters the services of one of the Dominions, will remain eligible for the full amount of compensation admissible.

The Committee is seeking an assurance from the C.R.O. that an officer's full service will in fact be taken into account by all Crown services to which I.M.S. officers may be transferred.

**Transfer of I.M.S. Officers to the National Health Service**

The Committee requested a ruling on whether an officer who accepted an appointment in any National Health Service would be liable to forfeit his compensation and receive only the resettlement grant of £500.

In reply the C.R.O. stated that full compensation would be paid to I.M.S. officers who accepted appointments with Regional Hospital Boards, local executive councils, or local health authorities so long as these were not regarded as permanent pensionable posts under the Crown.

The Committee is not satisfied that service in any National Health Service might not at some future date be held to be permanent pensionable service under the Crown, and foresees the possibility that an officer joining the new Service might subsequently be asked by the Treasury to refund the amount of compensation received in excess of £500. The Committee received no assurance that such an eventuality would not occur and is pressing the Ministry of Health for this assurance.

**Leave Pending Retirement (under Military Rules)**

The Committee asked for information on the policy of converting home leave into leave pending retirement, which in some cases has deprived officers of 4 to 6 months' leave. In the Committee's view it was thought reasonable that leave pending retirement should in all cases be dated from Aug. 15, 1947, or at least from the date on which the officers were notified that their services were no longer required.

The C.R.O. explained that all I.M.S. officers in military employment on leave at the crucial date had been offered the choice of returning to India for further service in that country or Pakistan, or of having their present leave converted into leave pending retirement. The C.R.O. defended this action by explaining that an officer was not permitted to take ordinary leave in the U.K. except on the assumption that he was returning to India, while the military rules provide that the 12 months' leave which may be granted pending retirement shall include the privilege leave standing to the officers' credit. Further, officers who declined to return to India were given the opportunity of going on leave pending retirement, dating from the commencement of their leave, or of going on release leave from Aug. 15, 1947—i.e., 56 days plus one additional day for every day of overseas service at appropriate Indian rates of pay.

**Review of Pensions**

The Committee urged that the pensions of I.M.S. officers be revised particularly in regard to the assessment of proportionate pensions.

To this the C.R.O. replied that approval had been given to the revision of I.M.S. pensions, and new rates, consisting of those contained in the 1945 Pension Code for medical officers of the Navy, Army, and Air Force, with an additional Indian element are now payable to officers of the I.M.S. If, however, in certain cases it would be more favourable for an officer that his pension be assessed on the old code, this would be done.

**Additional Pensions to Officers of the Rank of Colonel and Above**

The Committee urged that the regulations for the grant of additional pensions to officers of the rank of colonel or above should apply to officers who held temporary rank of colonel and above for the necessary period during the war.

The C.R.O. stated that it had been agreed that officers pensioned under the new code should receive increased pension in respect of paid acting or temporary service in a rank higher than their substantive rank on retirement, and that in the case of officers pensioned under the old scale substantive lieutenant-colonels who had held the acting or temporary rank of colonel with pay as administrative colonel should be eligible for additional increments of pension in respect of such rank.

**Compensation Awards**

In answer to specific questions on the mode of payment of compensation the Committee was informed by the C.R.O. that

considerable progress had been made in the payment of awards, and an assurance was given that those outstanding would be dealt with as quickly as possible. All grants of compensation will be free of United Kingdom income tax, and it is unlikely that any payments will be made in India.

**INSURANCE ACTS COMMITTEE**

A meeting of the Insurance Acts Committee was held on Dec. 4. Dr. E. A. Gregg was unanimously re-elected to the chair. The Scottish Subcommittee and the Rural Practitioners' Subcommittee were reappointed, and also the Insurance Acts Committee's nominee on the Ministry of Health Distribution Committee.

Much of the meeting of the Committee was concerned with the resolutions of the recent Panel Conference. These were considered one by one and appropriate action taken. Resolutions which referred to rural practice were referred to an early meeting of the Rural Practitioners' Subcommittee. Other resolutions were noted for further discussion with the Ministry. On the question of ensuring proper representation by co-option of medical practitioners on statutory health committees of local authorities it was stated that the Minister was fully with the profession on this matter. He would be informed of cases in which committees had failed to make such co-option.

A statement was made on the agreement with the Ministry of Fuel and Power concerning the use of petrol by members of the medical profession. The statement appeared in the *Supplement* of Dec. 6 (p. 132). The Committee accorded a vote of thanks to Dr. Wand, chairman of the General Practice Committee, and to Dr. Stevenson, assistant secretary, for their efforts in this connexion.

The position of medical members of local executive councils in relation to the provision of payment for loss of remunerative time in attending meetings of such councils was raised. The experience in this respect concerning members of the insurance committees appears to be diverse, but medical members of executive councils will be more numerous, and a new policy may be indicated. It was agreed to offer no advice to individual members with regard to such claims, but to deal only with the scale of payment allowed.

The future position of the Insurance Acts and General Practice Committees upon the inception of the National Health Service Act was briefly considered, and members were appointed to discuss the matter with members of the General Practice Committee and the Organization Committee.

It was reported that the sessional fee for part-time regional medical officers had been raised to three guineas for a session of two hours, with effect from Oct. 1 last.

The question of medical records of persons no longer entitled to medical benefit was considered on a letter from the Ministry of Health. The Ministry feels that it will not be possible in any new service to revive the old insurance medical records, and in view of the fact that these are at present occupying valuable space it is proposing to advise insurance committees that they may dispose of the records in question. Several members of the Committee expressed the view that an effort should be made to prevent destruction of these records, but eventually it was decided to ask that current records should not be withdrawn from doctors, the Ministry being left to make the decision regarding old records.

Dr. J. W. Bone, treasurer of the National Insurance Defence Trust, reported that during the last twelve weeks a sum of £46,000 had been received—a record income for such a period. The total amount in hand had gone up to just upon £450,000. He mentioned significantly large contributions recently made from some areas.

The Home Office announces that Dr. Brendan O'Carroll, of South Kensington, London, S.W., is no longer authorized under the Dangerous Drugs Acts to be in possession of or to supply dangerous drugs.

## PSYCHIATRY AND THE NATIONAL HEALTH SERVICE

A conference of the Psychological Medicine Group was held at B.M.A. House on Nov. 11, principally for a discussion on psychiatry and the National Health Service. The conference, at which there was a large and representative attendance, was presided over by Dr. W. G. Masefield (Eastbourne).

Dr. W. Rees Thomas, of the Mental Health Division of the Ministry of Health, addressed the meeting on the representation of psychiatry generally in the National Health Service. He pointed out that it had been secured in the Act that a certain proportion of members of the Central Health Services Council and the Regional Hospital Boards should be representative of the mental health services. Two of the fifteen medical practitioners on the Central Health Services Council were to be selected for their knowledge of mental illness and mental defectiveness. In all these bodies, including hospital management committees, it was specifically laid down that there should be consultation with the organizations concerned, and in the case of the management committees with the senior medical staff of the hospital, before appointments were made.

In a circular sent to local authorities it had been suggested that they and Regional Boards should make arrangements for some overlapping of staff; unless there was such co-operation the staff shortage would be accentuated. On child guidance he thought the view was accepted that there must be some division of authority; education authorities would continue to have their child-guidance centres, to which if necessary psychiatric advice might be forthcoming from the regional staff. The view of the Ministry was that at the child-guidance centre the visiting psychiatrist would attend only for diagnosis and perhaps short-term treatment. Any child in need of more than that would be dealt with at the child-guidance clinics established under the Regional Board.

### Functions of Regional Boards

Dr. Rees Thomas said that development of the mental health services had naturally been unequal in different areas, and it was not expected that the new health scheme would "spring fully armed" on July 5, 1948. Practitioners would presumably draw on the specialist service for consultations in the home. This service was already being carried on by some local authorities. Out-patient departments were slowly developing. There were some 200 adult clinics in the country, some almost entirely diagnostic, others not working frequently. Such activities ought to be one of the first developments of regional mental health services. As for in-patients, there were seven or eight categories of places in which they might be received: first, the mental hospital, the background of the mental health service; then the general hospital, in which, it was hoped, the psychiatrist would have a larger part to play.

Professors of psychiatry at the teaching psychiatric units, like other people who taught, must have beds. At some time in the future each university centre would have a psychiatric unit, with beds for teaching and facilities for research and for postgraduate training. It was expected that there would be a neurosis centre in each region large enough to justify the appointment of a first-class staff. Poor Law accommodation was the worst, but it included places for more than 10,000 people who would come within the care of the Regional Boards as cases of mental illness requiring care and treatment. For this purpose it would be necessary to take over a number of former Poor Law institutions, and in this connexion he hoped that old people would receive special consideration and treatment. What he had said about mental illness applied also to mental deficiency.

### Attitude of Lay Public

Dr. J. E. Nicole (a member of the Liverpool Regional Hospital Board) said that behind the question of policy was the question of the attitude of the community towards psychiatry and mental hospitals. To a large extent the establishment of the new Service would rest with the lay community, and the general attitude of that community would determine its character. The stigma of mental illness still lingered. For example, the person to whom it fell legally

to commit a patient to a mental hospital was a magistrate, a figure associated in the public mind with delinquency. In a new and much extended mental health service there might grow a tendency, already present to a certain extent, to deal with public prejudice against mental illness, certification, and mental hospitals by means of compromise, circumvention, and appeasement, with disastrous results to psychiatry and to the patients committed to its care. Such a tendency should be vigorously resisted as being inconsistent, medically unsound, and intellectually dishonest. To fight public bias and ignorance rather than appeasing it would be the only way to ensure that patients would be treated and classified on purely medical grounds and not in a manner designed to find an easy way out of the difficulties created by social prejudice.

Dr. Nicole wondered whether those interested in mental health had done all they could to educate members of town and county councils and public-assistance committees in the aspects of mental illness as they knew them. It was very necessary, in the disposal of in-patients, to avoid any indiscriminate classification and to oppose any policy of mere avoidance of mental hospitals. Attention must also be paid to rehabilitation in its broadest sense, remembering that adequate facilities for this might be extremely difficult to provide in some of the psychiatric units envisaged in the new Service. The new Service should afford an opportunity to overcome lingering prejudices and obsolete ideas on the subject of mental disorder instead of pandering to them.

### Hospital Management Committees

The conference then turned to questions. The first concerned hospital management committees: would there be psychiatrists on them, and if so would the psychiatrists be of medical-superintendent standing or "some dubious psychiatrist down the street"? Dr. Rees Thomas referred the questioner to the third schedule of the Act, which laid it down that the members should include persons appointed after consultation with the senior medical staff.

On a further question he said that child-guidance clinics which belonged to the local education authority would remain. Other clinics might come within the definition of voluntary hospitals. But he pointed out that if the education authorities undertook the full treatment of children suffering from maladjustment they would be doing it at the cost of the local authority, whereas it might be done regionally as part of the National Health Service.

Asked to what extent the local authority would continue to develop its services, Dr. Rees Thomas said that the answer must be left to different areas. There were a large number of local authorities and a small number of Regional Boards, and the position would differ according to circumstances. Local authorities, if they wished to do so, could employ their own psychiatrists; this was in fact being done by London. It was a matter for arrangement between the authorities and the Boards. What would happen to part-time psychiatrists he did not know. Much depended upon the definition of specialists which the new Spens Committee might formulate in its report. In reply to a question as to the functions of local authorities, he said that one was the prevention of illness, which was a matter of education. It was not, strictly speaking, for the local authority to undertake the education of its local practitioners: the only people to do that were the psychiatrists employed by the Regional Board.

Dr. I. H. Jenkins asked to what extent the membership of the Board of Control would be reinforced by experts in branches of psychiatry other than mental defect or psychosis. Dr. Rees Thomas replied that there were at present four vacancies on the Board, which furnished opportunity for such reinforcement.

### Private Work

A question whether a specialist in psychiatry might also do private work was answered from the chair by the remark that the specialist could apply to be put on part-time employment. Another question was whether a doctor running a hospital psychiatric clinic as well as doing general practice would be allowed to continue both jobs under the Service. A member of the Secretariat stated it would be possible for a practitioner undertaking general medical services to undertake at the same

## Association Notices

### SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1, 1948. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the first award of the Insole Scholarship of the value of £250 for research into the causes and cure of venereal disease.

#### Conditions of Award: Applications

Applications for scholarships must be made not later than Friday, April 30, 1948, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

### Branch and Division Meetings to be Held

**MARYLEBONE DIVISION.**—At 26, Portland Place, London, W., Tuesday, Dec. 30, 8.30 p.m. Agenda: report by Representatives on A.R.M., July, 1947; report by Lord Horder and Mr. Lawrence Abel on negotiations with Minister of Health; discussion of the following motion, "This Division deeply deplores the refusal of the Minister to accept the fundamental principles of the profession and to introduce amending legislation to the National Health Service Act, 1946. Accordingly this Division requests that, before the plebiscite, the B.M.A. Council will give the strongest possible lead to the profession not to accept service under the Act"; consideration of size of support required for successful opposition to the Act.

**SHROPSHIRE AND MID-WALES BRANCH.**—In Ballroom of Raven Hotel, Shrewsbury, Sunday, Jan. 4, 2.30 p.m. General meeting. Agenda: Discussion on National Health Service as finally decided upon by the Minister; Instructions to Representative prior to Representative Meeting in London. All medical practitioners in the area of the Branch are invited.

**WINCHESTER DIVISION.**—At Nurses' Home, Royal Hampshire County Hospital, Winchester, Sunday, Jan. 4, 11 a.m. Extraordinary General Meeting. All medical practitioners in the area of the Division are invited.

### Meetings of Branches and Divisions

#### KENT BRANCH

A meeting was held on Oct. 24, with Mr. W. E. C. Wynne presiding. Those present were Drs. G. R. F. Stilwell, F. C. Cozens, A. D. Broatch, P. Jacob Galikín, H. J. Hoby, A. V. Kelynaek, R. Prosper Liston, G. E. M. Meyer, G. C. Milner, E. G. Pringle, M. F. Prout, A. Talbot Rogers, D. M. Thomson, and J. O. Murray, and Mr. A. R. Jordan.

A letter from the honorary secretary of the Kent Area Committee, British Hospitals' Association, pointed out that the Kent Area Committee had passed the following resolution: "That this Special Committee (of medical representatives) of the British Hospitals' Association recommends the B.M.A. Council to consider the formation of a special subcommittee of the Branch Council (with appropriate representatives to be elected by hospital medical staffs) to deal at a county level with matters affecting hospital medical staffs." It was resolved that this resolution be approved and that a special subcommittee be set up, and that it consist of Mr. W. E. Heath, Dr. F. C. Cozens, and Dr. A. Talbot Rogers.

Dr. Talbot Rogers explained that the local medical and panel committee was the authorized body recognized by the K.C.C., and that so far the K.C.C. had decided not to co-opt medical practitioners. It was resolved that all steps be taken as an endeavour to obtain co-optation of medical representatives on the Kent County Council Health Committee.

It was resolved that Mr. A. R. Jordan and Mr. W. E. Heath be appointed representatives of the Kent Branch Council on the South-eastern and South-western Metropolitan Hospital Areas (Cancer Service (Cancer Act, 1939)).

### NORTHERN IRELAND BRANCH

A meeting of Branch Council of the British Medical Association, Northern Ireland, was held on Nov. 6, with Dr. T. A. Kean in the chair. Members present were Drs. Kean, Warnock, Boyd, Lyle, Boylan, Halliday, Andrews, Pyper, Hadden, Clarke, Smiley, Breen, Giff, Hemmingway, Hunter, Crozier; Messrs. I. Fraser and H. I. McClure.

Dr. Lyle inquired if the university members of Parliament had tabled the motion in the House of Commons in respect of the Topping Report. Dr. Halliday stated that on the advice of counsel this motion had been postponed and that a new clause had been drafted by counsel to be inserted after Clause 45 in the Health Services Bill to read as follows:

"The Ministry may prescribe the qualifications, remuneration and conditions of service of all or any of the officers of a health authority employed for the purposes of its functions as a health authority provided that in the case of a professional officer the Ministry shall consult such organizations as may be recognized by the Minister as representing the profession concerned."

In the past the Minister had always deplored the fact that he had not power to dictate to local authorities and other bodies. If this clause was accepted by the House and the Minister still refused to implement the Topping Report then the university members would bring forward their motion and have the whole question discussed in the House.

Dr. Halliday stated that it was of the greatest importance that a negotiating committee should be formed to meet the Minister to discuss the Regulations arising out of the Health Services Bill. This committee would not have power to commit the Association but would report to Branch Council, who would in due course seek confirmation of the Association. Discussion followed and it was agreed to nominate one general practitioner, one public-health officer, and one consultant or specialist from each Country Division. It was left to the discretion of the Divisional committees concerned whether these nominations were made by them or at a meeting of the whole Division. Dr. Hunter suggested that in the case of the Country Divisions where travelling distances would cause serious inconvenience due to petrol restrictions, etc., a Division could nominate members from another Division to act on their behalf. The Belfast Division owing to their much larger numbers would nominate four members from each group of the profession.

Dr. Crozier stated that the marriage bar imposed on women employed by the Northern Ireland Government had been discussed and a recommendation reaffirming the policy of the Association that in considering grounds for the appointment or dismissal of women medical officers marriage should not be made the reason for withholding or terminating an appointment. It had been agreed that a copy of the resolution should be sent to the Northern Ireland Government and to the Glasgow Corporation, which also adhered to the marriage bar.

#### PRESTON DIVISION

A B.M.A. Lecture was delivered on Dec. 9 by Prof. Ian Aird, of the London Postgraduate Medical School. Over seventy members were present, and Dr. W. A. Simpson, Chairman of the Division, occupied the chair.

Speaking on "Gastro-duodenal Haemorrhages," the lecturer declared that in such a condition where both physician and surgeon were concerned the importance of close team-work could not be overstressed. Careful selection of cases for operation was of the utmost importance. While operation should be resorted to only in cases where success was likely, it should not be used in cases which would recover under medical treatment. Referring to Meulengracht's exceptionally low mortality figures, he suggested that they might be accounted for by the inclusion of cases which did not in fact require operative treatment. In cases over 45 a second haemorrhage was an indication for operation, though older patients were bad operative risks. Local analgesia was recommended, though in younger patients gas-oxygen and cyclopropane might be used.

In determining operability the height of the blood urea was important and should always be estimated. Experiments on medical students who had blood poured into their stomachs by stomach tube showed a raised blood urea in these cases. This indicated that the mere presence of the blood in the stomach was a factor in the raised blood urea in haemorrhage cases.

A vote of thanks was proposed by Mr. Arnott and seconded by Dr. D. J. Davies.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

**County Borough Councils.**—Barnsley, Gateshead.

**Metropolitan Borough Councils.**—Fulham, Hackney, Poplar.

**Non-County Borough Councils.**—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, Walsend.

**Urban District Councils.**—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

**Scottish Burghs.**—Motherwell and Wishaw.

 — E. M. B.: *Aids to the Diagnosis and Treatment of Diseases of Children* 5th ed., 775  
 Allergy:  
 Book on, 534  
 — Infection (annotation), 740, allergy and the endocrine, 755  
 — Food, 100, 304  
 — Hay-fever, 475  
 — Infection, response to, 475

## ALLEGY (continued):

Penicillin: Allergy to penicillin with symptoms of serum sickness (A. G. Wilkinson and K. Zinnemann), 665 (O); correspondence, 974  
 Pollen, annotation on, 22  
 Primula, sensitivity to, 282  
 Pruritus ani as an allergic condition, 74

ALLISON, V. D. (and Betty C. HOBBS): Inquiry into epidemiology of pemphigus neonatorum, 1 (O); leading article, 19  
 ALLPORT, N. L. (and D. E. GARRATT): Metal contaminants in foodstuffs, 1051  
 ALLWORTHY, S. W.: Judicial hanging, 516  
 Almoners, future of, 843, 1011  
 ALSTON, J. M.: Poliomyelitis, 432  
 Aluminium and gastritis, 757  
 ALVES, Mary W. (and Idwal PUGH): Poliomyelitis: second attack, 904 (O)  
 ALYEA, Hubert N. (and Vincent J. BROOKES): *Poisons, Their Properties, Chemical Identification, Symptoms, and Emergency Treatment*, 256  
 American OSE Review, 249  
 Amethocaine, overdose of, 553  
 Amoebiasis, surgical aspects of (P. Theron), 123 (O); correspondence, 227, 269  
 Amphetamine, action of, 1018  
 Amputation, Ström's, case of bilateral (L. H. Cane), 211 (O)  
 Amyloid disease and rheumatoid arthritis: report of case (W. Yeoman and J. V. Wilson), 483 (O)  
 Amyoplasia congenita associated with hyperostosis frontalis interna (R. N. Herson), 491 (O)  
 Anaesthetic phase after recovery from injury, 815, correction, 1018  
 Anaemia, acute haemolytic (Lederer type), case of (G. Papayannopoulos), 371; correspondence, 590  
 — haemolytic, 542  
 — severe, due to diaphragmatic hernia (N. J. Rousvak and S. Eden), 733

## ANAESTHESIA:

Apparatus, safety, for administering trilete-and-air analgesia (A. L. Hyatt and others), 27  
 Artificial circulation produced by rocking: its use in drowning and anesthetic emergencies (F. C. Eves), 295 (O)  
 Books on, 134, 176, 373, 953  
 Chloroform, centenary of (Douglas Guthrie), 701; annotation, 699; correspondence, 783  
 Circumcision, 357  
 Closed circuits, remote control of (Norman R. James), 345  
 Curare in (John Gilles), 542  
 Cyclopropane, chemistry of, 357  
 Death, sudden, from causes associated with anaesthetics, 52  
 d-tubocurarine chloride, "unjustified" use of, 840, 976, 1009  
 Endotracheal flange (John Gordon), 784; correspondence, 930  
 Ether impurities (annotation), 61  
 Intravenous, safer administration of, 747  
 Spinal, meningitis after, 226  
 Thiopentone, convulsions under (R. I. Eodman and A. Farr), 175  
 Thiopentone-nitrous oxide-oxygen, with curare for head and neck surgery (J. G. Bourne), 654 (O); correspondence, 745, 788, 539  
 Trilete, chemistry of, 357  
 Urethane, 193  
 Vinethene, chemistry of, 357

Analgesia: Midwives and, 710—Intravenous procaine, 791—Local analgesia in dentistry, 942  
 Anastomotic ulcer 12 months after Semmervell operation (Harold Dodd), 170 (O); correspondence, 305  
 Anatomy: Amateur body snatchers (1855), 67—Bodies for dissection, 379, 403, 510, 590, 633, 858  
 ANDERSON, E. B.: H.T.S.T. pneumatisation, 927  
 — Robert: Foetal cries, 749  
 — T. (and J. B. LAMBERT): Oral penicillin in treatment of pneumonia in adults, 950 (O); leading article, 962  
 ANDREWS, G. S.: Case of traumatic recto-vesical fistula, 693  
 Anencephaly, re'e of, in nutrition of nervous system, 763, 933  
 Anonym and leukemia, 629  
 — thoracic, Babcock's operation for (F. T. Rawson), 692 (O)  
 Antena pedicels, 439, 585  
 Antipneumococcal oedema as possible sequel to penicillin administration (J. Owen Reid), 579

## Annotations:

Advance information, 1065

## OBSTETRICS:

Abortifacient pastes, 317  
Abortion: Treatment of inevitable, incomplete and septic abortion—analysis of 600 consecutive cases (J. McD. Connor and John Stalworthy), 89 (O); correspondence, 272  
—habitual, factors in, 305  
A.P. refill after childbirth, 1066  
Birth, premature, at sea, 272  
Books on, 372, 615, 658, 735, 950, 1035  
Child-bearing, some facts about (annotation), 460  
Eclampsia: A toxemia? 42—Lesion in renal cortex in, 706  
Emergency service at Newcastle-upon-Tyne (Frank Stabler), 878 (O); correspondence, 976, 1055  
Focal crises, 508, 634, 672, 710, 749, 931, 1011  
Foetus, endocrine, in a Fiji infant (R. W. D. Maxwell), 732 (O)  
Gastro-enteritis of unknown aetiology: outbreak in a maternity unit (G. T. Cook and B. P. Marmion), 446 (O)  
Haemorrhage, concealed: unusual case (W. Alford Taylor and Gordon Dutton), 419  
Hernia of diaphragm as complication of labour (Bryan C. Mullies), 251 (O)  
Induction of labour, 1017  
Labour, complicated, 895  
Lactation: Physiology of breast, 68—Iodine and failing lactation (Margaret Robinson), 126 (O); correspondence, 274—A lactation vitamin (annotation), 181—Loss of hair during, 757  
Maternity homes, closure of, 192  
—ward attendants, swabbing of throats of, 679  
Midwifery Working Party (Ministry of Health), 186  
Midwives and anaesthesia, 710  
Morbidity associated with induction of labour (annotation), 738  
Oxytocic action of ascorbic acid, 976  
Pain, relief of, in childbirth (M. I. Milne and E. R. Younger), 16; correspondence, 1055  
Pethidine in labour, 71  
Placenta: Removal of, 195, 318, 679—Spontaneous delivery of, in front of foetus without haemorrhage (M. Halden Lloyd), 522  
—retained, 589, 709, 975, 1058—Intravenous ergometrine for, 309, 396  
Pre-eclampsia: What is it? 984  
Puerperal sepsis, aetiology and prophylaxis of (Joseph W. Bigger), 599 (O); correspondence, 744  
Shock in obstetrics (W. A. Scott), 647 (O), 718  
Toxaemia, severe or eclampsia, with central placenta praevia (George Newbold), 997 (O)  
Tritene in, 805  
Tritene-and-air anaesthesia, safety apparatus for administering (A. L. Hyatt and others), 27  
See also Gynaecology

O'NEILL, T.: Synchronous combined total gastrectomy, 929.

## OPHTHALMOLOGY:

- Rates on better eyesight, 717, 806  
 Butot's spots, 681  
 Blindness in Scotland (annotation), 102  
 Books on, 58, 576, 657, 1000  
 Cataract, treatment of, 196, 404  
 Colour-blindness: signals for the colour-blind, 190  
 Colour vision: warmth and vision, 274  
 Conjunctiva: Myiasis of palpebral conjunctiva, 31—Necrotic changes in cornea and, 681  
 Contact lenses (C. G. Kay Sharp), 261; correspondence, 469, 589, 843, 978  
 Dark adaptation, 681  
 Glaucoma: DFP in (annotation), 100—Chronic, 404, 558  
 Iris, calcium deposits in, in case of secondary hyperparathyroidism (C. Poniedel), 691 (O)  
 Lazy eye, 310, 398, 469, 588, 796, 933  
 Leslie Dana Gold Medal awarded, 849  
 Night blindness, 681  
 Oculogyric crises, 196  
 Ophthalmia neonatorum, penicillin therapy in (Arnold Sorsby), 322 (O)  
 —primary meningococcal (F. N. Shuttleworth and J. G. Benstead), 568 (O)  
 Poliomyelitis, ocular symptoms of (annotation), 620  
 Presbyopia, correction of, 597  
 Pupils, unequal, 1017  
 Refraction testing, 842  
 Vision, physiology of, 69  
 Xerophthalmia, 681

- Ochritis: As complication of Bornholm disease, 49  
 —After mumps, 120  
 Order, Venerable, of Hospital of St. John of Jerusalem: Promotions and appointments, 268  
 Orthopaedics: Pneumatic bone saw, 67—Cineradiography in orthopaedic surgery (Leon Gillis), 140 (O)—Books on, 256, 774—Suturing the fractured olecranon (F. J. Fairbank), 822  
 Ostr, Bernard L. (and others): *Practical Physiological Chemistry*, 12th ed., 329  
 Osteoarthritis: Plasma viscosity in, 686—Of hips, 717  
 Osteomyelitis, acute, treatment of, 30, 924  
 —of femur, 1017  
 Osteotomy, nitrogen balance after, 814  
 Oswald, Neville: Expectoration of shell fragment after 29 years, 455

## OTOLOGY:

- Audiometry: The peep-show—a new technique for pure-tone audiometry in young children (M. R. Dix and C. S. Hallpike), 719 (O); annotation, 738  
 Book on, 456  
 Deaf-mutism in Switzerland, 703  
 Deafness: Schools for the Deaf, 155—In young children (annotation), 738  
 Hearing-aid, M.T.3 ("Midget Telephonic Three-stage"), 145, 710—And audiometers, 893—Ministry's hearing aid (annotation), 916—In the tropics, 941  
 Otitis media acute, place of chemotherapy and penicillin in the treatment of (Geoffrey H. Bateman), 27  
 —recurrent, 281  
 —suppurative, bilateral chronic with complications (A. Mackenzie Ross), 56

- OUTHWATT, James E.: Iodine and falling lactation, 274  
 OXLEY, James: Anti-histamine drugs for pruritus of jaundice, 749  
 Ovary, fertilized abdominal implantation of (Edward L. Nicolson), 998  
 OWEN, F. C.: Calcium requirement, 787  
 OWEN-LLOYD, F. (and Delafont Roberts): Congenital defect of left diaphragm with volvulus of stomach and transposition of viscera, 485 (O)  
 Oxygen Inhalation, 120  
 —poisoning in man, 70, 226, 396  
 —unit for newborn infants (P. C. D. MacClanely), 970

## P

- Pandatrix four hundred years ago (H. R. E. Wallis), 26  
 —arterial (annotation), 182  
 Pate, Charles Max (and others): Memorial to Walter Reesley Bristow, 924  
 —J. D. *Abnormal Psychology*, 1001  
 Pelvic Character, distribution, and duration of, in Bornholm disease, 48—Discussion on, 464  
 —pelvic Sympathectomy and intraspinal alcohol injections for relief of (J. P. Greenhill), 859 (O); Relief of pain in intractable cancer of pelvis (M. K. K. and J. G. O.), annotation, 875; correspondence, 974, 1057  
 Pate, A. B.: Recurrent dislocation of shoulder, 924  
 —"Pain" feet" or Gopalan syndrome, 165, 764  
 PATEL, R. V.: Treatment of neurosyphilis, 724  
 Patten, — abdominal, method of (F. W. Price), 703; correspondence, 839  
 Patten, cerebral, review of book on, 694  
 Patten, discoverers honoured, 39

- Pancreatitis, annotation-on, 580  
 PANDALAI, K. M. (and Mariam George): Possible mode of action of penicillin, 210 (O)  
 PANNETT, C. A.: *Surgery: A Textbook for Students*, 2nd ed., 775
